## INDEX.

Throughout the Index the following abbreviations are used to indicate the nature of the reference:—

(Pat.) Patent News. (Cor.) Correspondence. (Soc.) Societies' Meetings. (Rev.) Review or Trade Notice. (Ans.) Answers

The Index includes several Sub Indexes—

Bankruptcies, Companies Registered, Exhibitions, Obituary, Patents (Authors of),  
which are placed in their alphabetical positions.

	PAGE
ACADEMY, The Royal	384
Accessories, indoor	823
Acetylene—feed generators	399
Acid fixing bath (see fixing bath)	727, 778
Actors' Association, reputation to P.P.A.	395, 410
Actresses' photographs	136, 156
Advertise. By Pirie MacDonald	1013
Advertisements, designing camera in	362
photographs for (Cor.)	878
Advertising, aim in	32
photographers local (Cor.)	107
questionable	82
town's photographic	425
Aerograph new premises	45
the word	44, 759
work (Ans.)	40
Agreements, photographers' and assistants'	903
Air bubbles in modern lenses	208
waves, the effect of	6, 1
"Aitchison" prizes for optics	878
Albumen paper, stripping bichromated	261
(Met) papers T. & M. (Rev.)	176
versus gelatine	565
Alcohol, industrial	453, 582, 783
Aizarine blue S (Soc.)	338
Alkali and reducer, the action of the relative	270
weights of. By A. & L. Lumière	246
Alkalies in organic developers, action of	270
relative weights	962
Almanac, British Journal, 1907	522
Aluminium as fogging agent	573
Alums and aluminium salts on gelatine. By A. & L.	974
Lumière	567
American Annual of Photography, 1907 (Rev.)	974
American magazine, notes on reading. By W. J.	947
Casey	716
American Salon, the	56
Amber bottles	323
Ammonia, deaths from	294
Anachronisms in art	472
Anastigmat "Aida" (Rev.)	734
lantern lens	230
"Pantar" (Rev.)	756
"Solar" and "Combinar" (Rev.)	1015
Watson "Holostigmat" (Rev.)	770
Aniline dyes as printing inks. By E. Valenta	267
Annan, J. Craig	881
Aperture, angular	123
varying in lenses	23, 164, 198
accurate marking	496
Are lamps, enclosed	249
"Jandus Enclosed (Rev.)	278, 918, 939
reflected, in studio	178
Architectural photography (Soc.)	116
Arrowroot, Bermuda	472
Art, anachronisms in	564
craft, photography as	225
in painting and photography. By J. C.	202
Dollman	243
training of photographers	184
Artistic Lenses. By Demachy, Puyo and Pulligny	161, 103, 214, 252, 279, 283
"(Rev.)	373, 435
Exhibition at R.P.S.	915
Asphalt, action of light on	469
emulsification of	371
Assistants' certificates	482, &c.
(See Certificate Assistants)	
Assistants' protective society, photographic (Cor.)	907
wages of photographic	269
Astronomical photography	298
trust	982
Austrian process work at Earl's Court	464
Autoscope Co.	13

	PAGE
BABY contest, successful	404
Backgrounds	784
cloud (Ans.)	340
concave (Pat.)	455
distemper (Ans.)	860
hanging	474
material (Ans.)	739
natural	302, 346, 416
(Pat.)	472
variety in	102
Bacteria, differentiation by the photographic plate	547
By Walter C. Stevenson	417
Bacteria, luminous (Cor.)	
BANKRUPTCIES—	
Austen, G. W.	398, 499, 657
Birmingham & District National Trading Co.	355
Brightman, H. E.	437, 533, 1037
Blases, T.	738
Brown, F. A.	857
Draycott, A. H. S.	616
Draycott Galleries	336, 488
Ellis, E. E.	196, 218, 1037
Ellis, S. J. H.	783
Garside, R. C.	877
Gordon, J. T.	715
Hargreaves, E.	398
Harrison, W. M.	18
Hoffert, W.	298
Jacklett, E.	657
Keene, E.	355, 447
Margand, A.	635, 715, 957
Maytum, A. R.	498
Morris, C. F.	179
Newstead, P. E.	233
Norris, C. E.	130
Parkin, T. E.	298
Pearce, B.	235
Porter, S.	596
Puetz, C. H. W.	577
Shedle, A. D.	518
Temple, F. C.	117
Van der Weyde	577, 657
Weatherley, A.	308
West, J.	156
Wren, G. E.	95
Barnett, Mr. Walter in America	31
Bathed plate, orthochromatic work and the (Soc.)	965
Belin, M. Edouard	972, 985
Rennett, photographs by Mr. H. W.	914
Bichromated gelatine, properties	29, 130
(See also Carbon)	
Binoocular microscope, Abbé's papers on the	41
Risulphite lye	311
Blackening inside of camera (Ans.)	159
Blanchard brush	962
Blenheim Club, studio	1087
Blinds, studio	350
Blocks, curved (Pat.)	954
process resistant (Pat.)	913
(See also Half-tone)	
Boagus photographers	493
Bolt Court School report	277, 293
"Bondman, The," photographs of	817, 938
Borax as preventive of spots	208
Border negatives (Pat.)	654
film (Rev.)	316
Bottles, photographing	776
Brilliance of negatives, loss of	562
British Museum. Photography at the	453, 1001
Bromide emulsion for the printing-out process. By	466
E. Valenta	208
Bromide paper, acid developers	295
"Bromona" Ilford (Rev.)	1016
"carbon surface" Wellington	835
(Rev.)	94
Criterion (Rev.)	657
invention	94
Kodak "Velvet" (Rev.)	657
Metalline "Silvo" (Rev.)	93

	PAGE
Bromide printer (Pat.)	132, 1034
"Hana" (Rev.)	655
(Pat.)	695
"Renaud" (Rev.)	113, 513
"Sickle" (Rev.)	71
Bromides, bleaching (Cor.)	339, 358
blisters in toning	243
blue tones	505
invisible (Pat.)	472, 992
sulphide toning	646, 872
chemistry	219, 947, 971, 997
toning	276, 682
By Dr. Sedlacek	624, 646
"Loto" solutions (Rev.)	35
prints yellow fog	310
Brussels Process exhibition, awards	454
Bubbles, air in modern lenses	208
Buckle, brush	969, 965
Burton, optician	358
"Business, How to Buy" (Rev.)	375
methods of getting	408
tactics. By F. Dundas Todd	690
and saleable portraits	427
topics	483
CAMERA CLUB, proposed West-end	397, 493, 1013
Camera for colour photography. By E. J.	105
Wall	16, 316, 504
"Camera Work" (Rev.)	313, 393, 455
Cameras (Pat.)	554
"Century" (Rev.)	993
counting mechanism (Pat.)	514
film (Pat.)	1014
finder (Pat.)	514
lens-plane "Elite" (Rev.)	433, 514, 638
folding (Pat.)	993
hand (visible focussing) (Pat.)	635
Kodak No 4a (Rev.)	114
"Quick Focus" (Rev.)	412
movement (Pat.)	513
multiple-exposure (Pat.)	71
"Palms Universal" (Rev.)	777, 797
reflector (Cor.)	413
Premo (Rev.)	413
Graflex (Rev.)	175
Thornton-Pickard (Rev.)	685
Cameron, Mrs. Julia, Photographs	704
by F. C. Tilney	2
Canvasser with portfolio	979
Canvassers, photographers, assistants, and (Cor.)	196
Canvassing business, pleasures of	130
how worked	18, 37, 136, 297, 518, 517, 836, 975, 945
cases	17, 19, 75, 198, 903, 932, 997
frauds	958
"B-fast"	917
fighting the Cor.	982
Perth and Romsey	972
Sheffield	973
trade (Cor.)	457
(See also Carbon Frauds)	
Caramel-Boryl (Rev.)	847, 363
Carbonates as developers, double. By Matthew	22, 103, 142
Wilson	159
Carbon printing	182, 193, 392
(Ans.)	283
process (Bühler)	822
double transfer	553
on glass	623
invention of (Cor.)	394
sensitising tissue	955
(Cor.)	422, &c.
tissue (Pat.)	
(See also "Pigment Tissue")	
via bromide	310

### SUMMARY.

The index for 1905 is presented with this issue.

Hatched vignette negatives are suggested as an alternative of much indifferent vignette printing. (P. 2.)

A portfolio of prints, personally submitted, is put forward as a possible means of attracting business. (P. 2.)

A review of the photographic year 1905 itemises the outstanding advances and comments on the somewhat colourless character of the past twelve months. (P. 3.)

A tested formula for a universal developer adjustable to various purposes is given on p. 4.

The first of two articles on stationery for professional photographers appears on p. 5.

New instructions for the making of lantern slides in three-colour and monochrome by the Pinatype process are given on p. 6.

Archibald Cochrane, in an address on the "Pictorial Aim in Photography," urged the selection of sufficiently important subjects treated with feeling and produced with very little hand work. (P. 8.)

Some simplifications of lantern calculations have been drawn up for the guidance of exhibitors. (P. 11.)

A number of modified formulae for the development of P.O.P. have been worked out by two German workers. (P. 11.)

Should the photographer use paintings instead of photographs in the decoration of his reception-room? (P. 12.)

A machine for continuous printing, on bromide and other papers, from drawings and flexible negatives, is described and illustrated on p. 13.

The Zander complementary colour process is described from official data. (P. 14.)

A developer containing a chromium salt has been patented as a means of conducting development at a higher temperature. (P. 15.)

Improvements in cotype printing are among other patents of the week. (P. 16.)

## EX CATHEDRA.

### The Year's Index.

With this issue is presented the index to the past volume, the compilers of which, so we hope and believe, have escaped the glaring commission of those sins for which readers ever heap anathemas upon the heads of indexers. To index by subject, in place of, or as well as, by title, should be one of the golden rules of the conscientious indexer, who, needless to say, ought to know the subject he is at work upon. If it were followed, we should be spared such cases as one which came under notice quite recently. There was occasion to refer to an article on slider cranks in an engineering periodical. The searcher had a distinct recollection of its appearance, but the indexes for the ten years near the probable date of its publication gave no trace of it. There was nothing for it but to go through the volumes page by page. At length it was found to be not an article but a letter which the editor, querying certain of the writer's claims, had titled, "Does It?" And the indexer—wretched man!—had so entered it under D.

\* \* \*

### Aids to Reference.

Apart from avoiding entries such as the above we have had other aims before us in supervising the compilation of the present index to the BRITISH JOURNAL for 1905. One of these has been to prevent needless reference on the part of those looking up any given item. Usually the reader has some idea in what form the subject he is looking up appeared, as a society report, a patent, or a review. Therefore we have adopted the suffixes "Soc.," "Pat.," and "Rev.," to indicate—wherever such a course does not complicate the index—the nature of the entry. In addition the numerous historical paragraphs which have appeared under the heading, "The Week in History," are indicated by the suffix "Hist." It will be noticed that there are several sub-indexes, chiefly the one of authors of patents, which it is hoped will enhance the value of the bound volume of the B.J. for reference purposes.

\* \* \*

### One Moral of the Index.

Society secretaries may be interested in looking up the entries which are indexed under "Societies Meetings," inasmuch as in selecting these items we have had to decide between what was of general and lasting value and what possessed purely ephemeral interest. A large number of society reports are necessarily left unindexed, and those which are included will be found in almost every case to be the sort of report which is worth printing week by week. The duties of a society reporter, as we took occasion to point out some time ago, are more important than is often believed. An indirect proof of the benefits which

he can extend to his society is contained in the fact that the greatest number of noteworthy reports emanate from the most active societies, the executives evidently recognising that nothing is lost, but much may be gained, by letting their activities be known.

\* \* \*

**Character in Portraits.** The confessions of the Parisian portrait painter, M. Theobald Chartran, as elicited in the current issue of the "Pall Mall Magazine," may be studied by photographers who aim at character rendering. M. Chartran finds a definite typical expression to run through a nation. In Americans he notices a certain expression in the eyes and a knitting of the brows which stamps the subject with his nationality, and appeals to the painter as the result of the tireless Transatlantic activity. Perhaps, also, the difference between portraits of Englishmen and Americans is explained by the habit of the latter to assume consciously an alert, aggressive expression, while the former prefer to withdraw into an attitude of reserve, and require all the tact of the photographer to resist the stupefying influence of the camera.

\* \* \*

**Hatched Vignettes.** For some few years past vignetted portraits do not seem to have been so much in favour with the public as they were a decade or two ago. This is not altogether surprising, so far as, say, cabinet-size pictures are concerned, seeing the wretched things that have been, and are being, turned out under the name "vignette." It is noteworthy that, although small vignetted portraits are not so much in favour as they were, by far the larger proportion of the enlargements now produced are vignetted, but the vignetting is of quite a different character. It is clouded or shaded, and sometimes there is an indication of hatching, as in the case of the celebrated "Richmond heads," quite different from the pear-shape shaded bust one so frequently sees at the present day in small pictures. At one time photographers paid great attention to the vignetting of their portraits, and printers skilled in this work were paid good salaries. Now the only practice seems to be to place a pear-shape or oval mask some distance before a bust portrait negative and print it, quite regardless as to whether that shape is suitable to the subject or not. If, in the vignette, a few sketchy hatched lines were judiciously introduced, after the style of the Richmond heads just mentioned, the picture would often be more effective and attractive.

\* \* \*

**Hatched Vignettes in the Camera.** Some forty years ago the late Napoleon Sarony introduced, and patented, a method of producing photographs similar in appearance to crayon drawings, known as Richmond drawings, and crayon heads. As a brief description of the methods used by Sarony may serve as hints to those on the look-out for novelties, we here give them as they appear in the official abridgment of the patent: "I effect this by a double process of vignetting direct in the camera. Firstly, I produce the bust of a person sitting, or other object required: vignetting that portion only that is seen in the finished picture by the use of a properly graduated glass suspended within the non-focal rays of the posterior lens, thus protecting certain portions of the sensitive plate from the action of the light; secondly, I place before such portion of the said plate as has already been acted upon by the light an inverted or reversed vignetting glass in such a manner as to secure the said part from any further action of light, while that portion of the plate previously unacted upon is now brought into the focus of a drawing which is placed before

the lens, and which represents the aforesaid Richmond drawing, the result being a scroll vignette or portrait." Another method of Sarony's was by double printing. In this method the portrait was first vignetted by printing in the ordinary way. Then a second negative, which was a copy of "the hatching or sketchy lines photographed upon the glass from a chalk pencil of such lines" was made. This negative was used for the second printing. Still another method of producing the hatched line negative, for double printing, was to coat a glass plate with black varnish and scratch the lines through this latter. Of course, the production of the vignetted negative in the camera involved extra trouble on the part of the operator, but when the negative was obtained there was no after trouble in the printing, as no vignetting was required. It was simply printed out as an ordinary print. It seems somewhat strange that so little attention has been given to the production of vignetted negatives in the camera with the view of saving trouble in the printing—to say nothing of waste in careless hands.

\* \* \*

**The Value of Glass.** A somewhat interesting fact is noted in one of our German contemporaries, as to the enormously enhanced value of raw material, such as that used for glass when made up into microscope objectives. The front lens of a micro-objective does not weigh more than about 0.0017 grammes, and as the cost of such a lens is about 20 shillings, the value of a kilogram of them would be about 12 million shillings. The cost of the raw material for making this weight of glass is from twopence-halfpenny to fourpence, and thus, when worked up into the shape of a lens, the glass has been increased in value about fifty million times. Such disparity between the cost of the raw material and the manufactured article is probably a record in industrial technics. The manufactured lens is literally worth a good deal more than "its weight in gold," for a piece of gold of the same size would be worth about a halfpenny. Radium and some of the rare metals are about the only things that excel it in value.

\* \* \*

**Circulating Albums.** Two suggestions for the New Year which we think should prove satisfactory in almost any good business outside the largest towns are a circulating set of albums and a portfolio of work shown by a lady traveller. The canvasser, or tout, is associated with the cheapest class of trade, and unfortunately with the free portrait swindle. The ideas suggested are on a higher plane, and both have been employed successfully within our own experience. In the one case, a dozen substantial folding cases of albums of special pattern are prepared each holding about eight perfectly produced specimens. The album is contained in a cloth-covered box or case, to which is affixed a label bearing the photographer's name and address. The parcels boy distributes the twelve cases at twelve selected houses, and if each is wrapped in brown paper and addressed, so much the better. Within is a circular giving the prices of the work shown and any other information about the establishment, and stating that the album will be called for in two or three days. This method affords the entire family an opportunity of carefully examining the work at their leisure. The second suggestion gives an opportunity of showing a greater variety of styles, work not suited to insertion in an album, and more expensive coloured work or ivory miniatures. Apart from the quality of the productions, the selection of a suitable receptionist who can call on the best people in the locality with such a portfolio is the principal point. The personal interview is an advantage in several ways; the lady traveller can

see, for instance, where a little further effort will produce an order, and much valuable information is obtained, which should be recorded, as to the possibility of doing business at some later date, and the class of work most likely to be appreciated.

\* \* \*

#### Another Celluloid Fatality.

Of late years celluloid has gained an ill-repute, and that not altogether without reason, seeing the number of accidents, fatal and otherwise, for which it has been responsible, both in this country and abroad. On Friday last another fatality was added to the list—a man being burned to death at Southwark. The account, as given in some of the daily papers, was that three men were engaged at the Odol Chemical Works in packing some celluloid, when it became ignited and exploded. One of the men was blown into a corner, and his charred remains were found amongst the debris after the fire was subdued; the other two men escaped. In some previous accidents it has been alleged that the celluloid ignited spontaneously, and also that it exploded. In this case an inquiry will, of course, be held, and as there are two witnesses of the catastrophe, we shall probably learn how the accident really arose, whether the ignition was spontaneous combustion, if there was an actual explosion, or only a very rapid combustion. Celluloid has for some thirty or forty years been extensively used for domestic purposes—knife handles, serviette rings, keys of pianos, dressing combs, etc.—indeed, almost every article for which ivory was previously employed; but until the last few years we did not hear of accidents from it. Photographic dishes, too, have been in extensive use for some years, and, so far as we are aware, there have been no mishaps from them. But there is celluloid and celluloid; some kinds may possibly be of a more dangerous character than others, and it would be well to know which they are. At the inquest, if expert evidence is called, some light may, possibly, be thrown on this point.

\* \* \*

#### Winter Pictures.

With winter thick upon us, photographers—at least, those residing in the metropolitan district—have as yet had no opportunity of obtaining pictures of scenes under the snow. However, there have been many heavy hoar frosts, some of which have been very like a slight fall of snow in appearance. Such effects as these should not be missed by those desirous of securing pictures depicting winter scenes, for they seldom last long, even a few minutes of sunshine often sufficing to destroy them. To obtain pictures of hoar frost one has not to go far afield. A suburban back garden will often supply several subjects. A currant bush or an evergreen, for example, when covered with the brilliant rime, forms an admirable subject, particularly if there is for a brief time a little direct sunshine upon it. Such subjects form excellent pictures for the lantern and the stereoscope. In the latter, slides depicting hoar frost are exceedingly pleasing; a shrub or bush which, under ordinary circumstances, is a very uninteresting object, becomes just the reverse when covered with hoar frost. It is scarcely necessary to remind our readers that to obtain the best effects of hoar frost the plates should always be protected against halation by backing, as the slightest halo would very considerably mar the excellence of the picture.

UNDIGNIFIED HASTE in announcing any event is always reprehensible, but particularly so in the case of a public body, like the London County Council. A correspondent sends us one of a number of circulars he has just received for distribution from the L.C.C. School of Art at Camden Road, in which announcement is made of a class in lithography commencing September 18, 1905.

#### WHAT OF THE YEAR?

PHOTOGRAPHICALLY, the past year cannot be assigned any very distinctive character. It cannot be credited with ushering in any new epoch; rather, it has formed with the past few years a period in the history of photography in which progress is less obvious because more widely disseminated. Existing processes and apparatus have reached a point at which any innovation must be highly novel to attract attention, and then it is frequently the case that the novelty turns out of little use in practice, having very probably been left alone by a previous worker as not worth elaboration. Nineteen hundred and five cannot claim to have been the sponsor to any published process or article of manufacture which has set the photographic world talking and working, as did, say, the new developers of the metal class or the modern anastigmats at their respective inception.

In the way of sensitive materials the market has enough and to spare of goods which conform closely to the present demand. Probably few photographic dealers would regret a P.O.P. or gaslight paper less; and as for a new brand, the dealer must stock it—even on the most limited scale—in that number of packets representing the permutations usually of three tints, two surfaces, and at least three or four sizes. Hence the increasing difficulty which minor modifications of plates or papers experience in reaching the goal of the shop counter, and hence the fact that an article must have very distinct and verifiable claims to novelty to obtain new entrance into commercial channels. These considerations, which are the natural causes of the paucity of commercial technical advances, may be commended to the study of persons who imagine photographic manufacture in a small way to be an easy road to wealth. It can be shown that certain printing papers can be made at extremely advantageous cost when the output is quite small, and thus, deceived by anticipations of a share of the photographic trade, small men will begin to manufacture, with the encouragement frequently of a party whose formula is the alleged key to wealth. There is one piece of advice which we give to such persons—namely, to get the views of a photographic dealer on the reception he (the dealer) will give to a new paper to be sold strictly without the hall-mark of an established firm and without the power of advertising. The answer is usually cold comfort to the prospective maker. But this counsel to self-deluded people is aside from our present purpose of looking back over the year which has just closed.

Of apparatus, if we except several hand cameras and accessories, the record of a reviewer must be that minor modifications of pattern sum up the situation. As a rule, the latest pattern of a camera is the best, and we have been gratified by seeing the infinite pains which some makers of the higher class instruments have expended upon their productions, yet it is easy to see how makers have also introduced movements and accessories merely for the sake of introducing them, and in some instances to the positive disadvantage of the camera. Apparatus of this kind we suppose is the inevitable response for something new, though to our thinking it must impress many a purchaser as got up primarily to sell, with its efficiency for practical work as a secondary consideration.

Turning to the technical advances of the year, probably the most distinctive are those in the field of orthochromatic sensitizers. Dr. König has added to the series of isocyanine dyes the bodies pinaverdol, pinacyanol, and dicyanine, and he and other investigators have examined the conditions under which these new sensitizers are to be employed.

Among processes concerned in the making of a negative

there is little to record beyond the examination of the bichromate intensifier by C. Welborne Piper and D. J. Carnegie, and the introduction of the cobaltamine reducer of negatives and positives which is now on the market. In printing processes the topics of the year have been self-toning P.O.P. and the sulphide toning of bromides. The latter method, after having worked its way through a number of formulæ, appears to have settled down to the use of a mixed solution of potassium ferricyanide and potassium bromide as the bleaching agent, followed by the solution of sodium sulphide for imparting the sepia tone. This procedure has proved to be that most suited to the commercial output of toned bromides. Mention should also be made of the processes of printing without light introduced under the name of catatype by Drs. Ostwald and Gros in 1903. Catatype processes depend on the catalytic action of the silver or platinum of a photographic image, and while thus far no practical use appears to have been made of the method, the sealing of patents claiming improvements in it points to its future possibility.

In colour photography we have had the usual crop of processes enjoying the brief celebrity of newspaper paragraphs, while among the methods claiming serious attention Dr. König's "pinatype" has re-inspired interest in

the printing of trichromes from gelatine plates by extraction of dye therefrom. Professor Lippmann has published a method of preparing interference colour photographs on bichromated films which holds out the hope of multiplying prints in colours by contact printing. Cinematography still awaits its long prophesied alliance with colour photography, and although the projection of animated photographs in natural colours which we have witnessed left us in no doubt of the practicability of taking and projecting the films, the public use of the process remains in abeyance. Meanwhile the work of education is immeasurably lightened by the applications of the cinematograph to the teaching of natural science initiated jointly by Mr. Chas. Urban and Mr. Martin Duncan. In artificial lighting the mercury-vapour lamp has come forward during the past year to strengthen the hand of the professional photographer. With its many obvious advantages it is yet too early to say if it exceeds in efficiency the enclosed type of electric arc lamp. Our retrospect has singled out what seem to be the outstanding items of 1905, an unnecessary performance, perhaps, on behalf of those who have studied their weekly journal, yet one which, in a year or two's time, will be instructive in showing the present position.

## A UNIVERSAL DEVELOPER.

AN exceedingly useful and universal developer of excellent keeping qualities may be made by suitably mixing a concentrated hydroquinone single solution developer with a metol developer of equal strength. The formulæ I have been using, and which would be hard to improve upon, are as follows:—

1. Water .....	20 ounces.
Hydroquinone .....	$\frac{1}{2}$ ounce.
Sodium sulphite .....	4 ounces.
Sodium carbonate .....	$7\frac{1}{2}$ ounces.
Potass. bromide .....	1 dram.

For use, one part of this should be mixed with three parts of water.

This is a complete developer, which gives an immense amount of contrast, but is very slow in action.

2. Water .....	20 ounces.
Metol .....	3 drams.
Sodium sulphite .....	$3\frac{1}{2}$ ounces.
Sodium carbonate .....	$3\frac{1}{2}$ ounces.
Potass. bromide .....	10 grains.

For use, one part of this is mixed with three parts of water.

This also is a complete developer, but is exactly the reverse of the former in action, yielding a very soft negative, full of detail and gradation with a minimum exposure; in fact, it is surprising how good a result can be obtained from what might reasonably be considered a hopelessly under-exposed plate. For plates exposed by artificial light, both in studios and flashlight interiors, it is invaluable, and gives results which I believe could be obtained by no other developer.

For use these solutions should be made up in the working strength already mentioned, and mixed in equal quantities when a really excellent normal developer will result, which may be used for a great number of times, and by varying the quantities of either, any desired effect may be produced with the greatest ease, or any subject easily treated to the best possible advantage without the slightest risk of chemical fog, which is so often the result of forced development by the usual method. In treating an over-exposed plate, which has been found to appear too quickly in the normal developer, the

hydroquinone solution may be used as a re-developer, and, if applied quickly enough, and the over-exposure be not too great, a perfect printing negative will result, and vice versa, of course, for any which do not appear quickly enough. For all makes of bromide and "gaslight" paper excellent results may also be obtained, but it is advisable to dilute still further for bromide. A good method of treating enlargements is to first develop in the metol, diluted with six parts of water instead of three, until all possible detail is out, and then to place without washing into the normal hydroquinone, when it will gradually attain all the vigour desired. This second development takes some little time in comparison with the former, but it will not be found to stain unless carried to an extreme, and yields such a pure black as to repay fully the little extra trouble. Gaslight prints are best developed in a mixture of three parts of the metol (normal strength) to one part of the hydroquinone (normal strength), or varied according to brand of paper employed; but with very few kinds will it be found advisable to dilute to any great extent, unless, of course, it is desired to obtain a soft print from hard negative, when the metol alone may be used, well diluted. These remarks also apply to lantern plates, and for making transparencies from which to make enlarged negatives. For copying very old or badly faded photographs this developer, with a process plate and a full exposure, will yield an astonishingly good negative. It should be borne in mind that any hydroquinone in the hypo will cause chemical fog, or yellow stain, so a good rinse before placing therein is advisable, especially with bromide paper. Also, I should recommend an abundance of pure, fresh hypo in preference to the popular acid fixers.

The formulæ given are not original, but selected, with slight alterations, from numerous ones in existence, and will be found to combine to perfection, and fulfil their respective duties as well as could be desired. A good pyro developer well restrained also acts well in conjunction with the metol in place of the hydroquinone, but is no better, and more expensive, as the developer quickly discolours, and is not safe to use more than once or twice, and a greater quantity

of pyro is necessary for use as a re-developer. A great many photographers will not consider anything but pyro as a developer for plates, but if some of that opinion will be persuaded to try this, they will find it equal in every respect and on an average to yield a quicker printing negative, to

say nothing about the greater economy and rapidity of action. It also has the advantage, as before stated, of being of universal application, which is a great blessing where occasional bromide work is to be done, or an odd lantern transparency to be made.

W. SHENTON.

## PHOTOGRAPHERS' STATIONERY.

### I.

From time to time the plea is raised on behalf of the work turned out by the average professional that any shortcomings it may have judged from an artistic standpoint are not due to his inability to produce something better, but rather to the fact that he is compelled to supply that which is in most general demand on the part of the public to whom he appeals. To a great extent there is truth in this, but the same defence cannot be advanced for the want of taste which is shown by too many photographers in their stationery, be it correspondence or advertising matter. Most business men nowadays admit that it is good policy to let the stationery represent as nearly as possible the standing of the house from which it is sent, and therefore that of the photographer should unmistakably convey the impression that he is the possessor of that quality which, difficult to define, is conveniently summed up in the term, "good taste."

Although much may be attributed to the desire to be "in the fashion," there still remains abundance of proof that the general standard of taste is considerably higher than it was twenty or thirty years ago. The building, decorating, and furnishing of our houses to-day all bear witness to this, while a still plainer proof is afforded by the character of the posters on the hoardings in our streets. This change is not so much due to any increased knowledge or ability on the part of those responsible for their production, as it is to the more refined ideas of the public, which shows that it appreciates the more artistic appeal to the senses. Papermakers and typefounders are fully aware of this—so much so that the good printer has sufficient material at his command to enable him to produce really fine work—such that, when used by the professional photographer, the recipient is at once impressed with the idea that it emanates from a studio in which good taste prevails. It is, of course, recognised that not every photographer caters for the class likely to be impressed by stationery of this description, but seeing that the very cheap trade involves neither making appointments nor giving credit, the necessity in such businesses for any correspondence with sitters will seldom arise, and it therefore follows that any photographer who has to correspond with his sitters will do well to consider the appearance of his stationery.

#### The Note Paper Used.

The photographer should remember that he is, or ought to be, an artist, and therefore his notepaper should not in any respect be inartistic—paper, type, ink, and the arrangement of the matter should all harmonise. Any illustration used should be both appropriate and well executed, yet one member of the P.P.A. uses a letterhead on which appears a representation of a pierrot photographing a pierrette, a banner over the two bearing the legend, "High class Photography," while a photographer in the Black Country uses a crude woodcut depicting a ruined archway and street in what is apparently an Italian village.

The quality of the paper itself is the first consideration, and seeing that the difference in cost between good and poor paper is so small it is as well when ordering the printing to

obtain prices for the work on various samples of paper. The wording of the heading has next to be arranged. One fault to be avoided is that of crowding in too much matter. Many photographers seem to forget that having a photograph taken almost necessarily involves a visit to the studio, or they would not set forth on their notepaper an amount of information which, if wanted at all, it is the duty of the receptionist to give. The stationery of the wholesale firms—the dealers, manufacturers, and trade-workers—must not be taken as an example. The photographer does not go to their warehouses, their travellers do not call on him more than three or four times a year, and so they are doing what is right when they use their notepaper for giving information about their business. "Enlargements a speciality" doubtless describes the willingness of the photographer to supply enlargements, although it will hardly do to apply the same line of reasoning to the announcement, "Children a speciality." "Old and faded photographs copied equal to new" is either untruthful or else an admission that one man's copy of negatives are as good as another's originals. "Enlargements in bromide, carbon, and platinotype" does not convey much more meaning unless the reader has dabbled in amateur photography, in which case he is likely to be puzzled by the "carbonettes and platinographs" announced by another photographer. "Photographing of dead bodies undertaken" may possibly bring in a commission once in a twelve month, but imagine the feelings of a young bride receiving a letter with reference to the photographing of her wedding group, upon noticing this cheering information. "A large stock of pictorial postcards" is another frequently used phrase. Where the possibility of securing the business by thus advertising on the letterpaper is so small, it is far better to aim at the reputation which is to be obtained by the use of a dignified and artistic heading. The commercial and technical photographer in a city who looks to business men for his commission does right in enumerating the various kinds of work he is prepared to undertake, but the average professional has no need to cover half his paper with wording of the above-mentioned description. At one time the possession of medals was something of which to be proud, but the increased number of photographic societies holding exhibitions and making awards has made medals so plentiful that it is hardly worth while mentioning them on the stationery. If the business be an old-established one, the fact may be embodied in the heading, thus: "Established over a quarter of a century," or "Established in the year 1870."

#### The Heading.

What information is the recipient of a letter from a photographer most likely to desire? The sender's name, what he is, and how to communicate with him by post, telegraph, or telephone; thus we have:—JOHN SMITH, Photographer, The Studio, 1, High Street, Northville. Telegrams, "Portraits, Northville." Telephone, "50, Northville." If Mr. Smith have branch studios in other towns, the heading should state "and at —," not, as is sometimes seen, two or even three addresses given with no means of distinguishing from which one the

letter is sent. The public generally applies the term "artist" to painters, and, therefore, if the photographer be prepared to accept commissions for paintings, the designation "Photographer and Artist" looks well, or, now that miniatures are so much in vogue, instead of "Artist" there may be substituted "Miniature Painter." Some of the leading American photographers use the expression "Maker of Portraits."

#### How to Print the Wording.

Shall it be in one or two colours? Printed or embossed? With or without illustration? With a good printer the two colours will be an improvement, but the ordinary printer is more likely to be successful with one. An embossed heading almost always looks well, especially if the user has the right to some crest or other device. Embossing is more expensive than printing, but the stationery thus treated may be reserved only for correspondence with sitters, plain printed paper being used for all other purposes. A good printer by judicious setting is able to make a very effective heading with plain type and "rules" alone, but there are printers *and* printers! Many, if left to their own devices, will insert all sorts of so-called "ornaments," ranging from representations of flowers and birds to motor-cars, and the illustrations of the "pierrot" style already mentioned. A number of photographers use headings in half-tone, the designs consisting either of views of the district or else portraits of pretty children, together with the name and address in suitable lettering. Although they do not bear the cachet of good form, nothing much can be said against these half-tone headings, except that to do the blocks, and, through them, the original photographs, justice, they have to be printed on highly enamelled paper, which has not a good writing surface. If something more ornamental than plain type be desired, it is better to have a specially drawn heading from which a "line" block can be made, and then printed on any class of paper. Such a heading printed in either one or two colours affords much opportunity for the display of good taste, but, except from printers who lay themselves out for high-class work, there may be difficulty in obtaining what is desired.

In the foregoing nothing has been said about cost, because prices vary so much, not only with qualities of paper, but also with the amount which is ordered at one time.

The envelopes should always match the paper, and should be of a size to take the octavo and quarto papers with one and two folds respectively.

#### System for Photographers.

Order makes for orders, and the photographer is well advised who adopts a good system of handling his correspondence. Letters received should at once have attention and, as soon as the reply is sent, be filed away so as to be of easy reference, in one or other of the numerous filing systems now on the market. If the replies are not copied, a memorandum may be made upon the letters themselves, or else in a scribbling diary, of the chief points. The use of the typewriter by photographers is gradually increasing, but many who buy them otherwise than direct from the makers, do not know that by using a sheet of duplicating carbon a copy may be obtained simultaneously with the original. Too many people seem to think that system is all very well in big concerns, but that there is no need for it in small ones. The idea is a mistaken one; the system need not be elaborate, but the small business man ought to relieve himself of worrying about details as much as possible, so as to leave his mind free for more important matters.

#### The Visiting Card.

The visiting card used by the photographer in making business calls should be of exactly the same style—that is, the small ivory card with square corners—as the ordinary private card, save that the usual "Mr." is dropped and the word "Photographer" added. One sees all sorts of cards more or less elaborate, deckle-edged, rounded-corner, and gilt-edged, but they should be avoided, there being no more room for doubt as to what is correct than there is as to what constitutes proper dress at any evening function.

#### The Billhead.

The form on which the account is rendered should resemble the notepaper as regards its being well printed, but it of course admits of more matter being added. The name of the bankers should be given. "Cheques to be crossed . . . ." While at the bottom of the bill there should be a footnote, "Extra copies or enlargements from this negative may always be obtained by mentioning the reference number . . . ." The gardee envelopes in which the prints are sent home may be made the medium for an excellent advertisement by being neatly printed, "A choice selection of frames suitable for this photograph always in stock."

A further article next week will deal with other branches of the photographer's stationery. W. J. CASEY.

## THREE-COLOUR TRANSPARENCIES BY THE PINATYPE PROCESS.

[THE Pinatype process, first demonstrated in this country at the last exhibition of the Royal Photographic Society, has been the subject of further investigation by Messrs. Meister Lucius, and Brüning, who have lately issued revised instructions for its use in the making of both three-colour and monochrome transparencies. The *modus operandi* will be clear on a perusal of these directions, a translation of which has been placed in our hands by Messrs. Fuerst Bros., who will shortly issue it in pamphlet form. The general instructions, to which reference is made several times below, appeared in our issue of September 22 last.—Eds., B.J.P.]

ANYONE who has already used the Pinatype process will at once see that transparencies may be made in various ways by means of the same; the following is an account of one of the simplest and most satisfactory methods.

Instead of using the commercial print plates, a suitable substitute can be prepared by anyone, if carefully cleaned glass is coated with the following bichromated gelatine. If this be used, it is obvious that they require no further sensitising; but the print plates must be sensitised before use, as described in the Pinatype instructions.

#### The Red Transparencies.

One of the sensitised plates should be printed under the negative taken through the green screen, but for rather less time than would be correct for a print on paper. After exposure the plate should be well washed till the drainings no longer show any tinge of yellow, which will be the case when all the unexposed bichromate is washed out. It should then be immersed for about one minute in a 5 per cent. solution of acid sulphite of soda or potassium metabisulphite, and then again washed for a few minutes. The action of this sulphite bath

is to remove the brown chromium compounds which are not soluble in water, and it may be used repeatedly, as it will keep for a long time in a well-closed bottle.

After washing the plate may be dried or used whilst still wet. In order to stain the same, the dye bath given on p. 24 of the instructions pamphlet should be diluted. 1 ounce to 2 ounces of water, and the plate immersed in this dilute solution and allowed to remain there till stained sufficiently deep; then it should be rinsed and hardened for about 5 minutes in the fixing bath given on page 26, and then washed and dried.

#### Preparing the Red and Blue Plates.

The red transparency should be placed face upwards on a levelled glass slab and coated with the following mixture in precisely the same way as is recommended for the preparation of the filters:—

Emulsion gelatine (best hard).....	77 grains
Water .....	3½ ounces.
Chrome salt .....	2 tablets.

The gelatine should be cut up into small pieces and allowed to soak in the water for about half an hour, and then dissolved by the aid of heat. The chrome salt tablets, crushed small, should then be added, and the mixture filtered through a fine linen filter. To every 16 square inches of glass from 67 to 84 minims of gelatine solution should be allowed.

The gelatine solution may be prepared and the plates coated by weak diffused daylight or artificial light. As soon as the gelatine has set the plates should be dried in a warm and dark place, free from dust. The coated plates will keep for several weeks.

The transparency taken from the negative through the red screen should now be superimposed on the red transparency, coated as described above with the bichromated gelatine, and the outlines of the images made to accurately coincide, which is much easier if a magnifying glass be used. The two glasses should be clipped together or temporarily bound so that they cannot shift, and then exposed to daylight of about two and a-half times longer than was necessary for the red image. This increased exposure is necessary, because some of the chrome salt penetrates into the red image and thus the sensitiveness of the upper film is lowered. Increase of the proportion of the chrome salt is not advisable, nor should any intervening film, such as a varnish of collodion or celluloid, be used.

After exposure, the plates should be well washed and then immersed for about 5 minutes in the acid sulphite bath and again washed, and then dyed in the blue solution. This should be made in precisely the same way as described on page 20 and diluted, 1 ounce to 2 ounces of water. When the image is sufficiently stained, it should be hardened as usual in the fixing bath, and then washed and dried.

#### The Reversed Yellow Image

The yellow image may be printed over the red and blue picture in exactly the same way as the latter was printed over the red, using the bichromate gelatine; it is, however, much simpler and easier to make a separate yellow image, and use the same as a cover glass for the transparency. Obviously in this case the yellow image must be reversed.

The necessary reversed transparency from the negative taken through the blue filter, which is used for obtaining the yellow

image, may be prepared either by using the Pinatype process, as described below, or by producing a reversed negative in the camera.

To make the reversed transparency by the Pinatype process, a sensitised print-plate should be exposed under the transparency from the negative taken through the blue filter for the same time as is necessary for making the yellow printing plate, and then well washed and dyed in the following bath:—

Pinatype black-brown .....	31 grains.
Water .....	3½ ounces.

When deeply stained the plate should be washed for a short time and dried. It is not essential to use the usual fixing solution, but if it is used the image will turn black.

In order to make the reversed negative in the camera, it is necessary to present the glass side of the sensitised plate to the lens, that is to say, to turn the film side away so that the image is formed on its lower surface. It is obvious that allowance must be made for this in focussing for all three images, and the easiest plan will be to place in front of the plates used with the red and green filters a sheet of clear glass of the same thickness as that of the plate used with the blue screen.

The reversed transparency is now used in the ordinary way for obtaining the yellow transparent image. The sensitised print-plate must be exposed rather longer than when preparing the yellow printing plate for a paper print. After exposure, the plate should be washed, treated with acid sulphite, and again washed, and then dyed. The dye solution is that given on page 25, which should be diluted with an equal quantity of water, that is to say, 1 ounce of dye solution to 1 ounce of water.

It is advisable to stain the yellow image at the same time as the blue image, because if they are both well rinsed from time to time, they may be temporarily superimposed and the correctness or otherwise of the depth of colour estimated. Finally, the yellow impression should be fixed or hardened as has already been described, and then washed and dried.

When the red and blue pictures are properly washed, the yellow transparency should be superimposed so that the outlines coincide, and if a larger sheet of glass has been used, then it should be cut down. If a print plate of the correct size has been used, it is, of course, only necessary to obtain coincidences of the image, to put a small dab of some mountant at each corner of the transparency, allow to dry thoroughly, and then bind up in the usual manner.

#### Lantern Slides in any Colour.

The above instructions deal with the production of transparencies true to all the colours of nature if the directions are properly carried out, but Pinatype places in the hands of the lanternist quite a new power, for with the aid of the special Pinatype dyes, which can be obtained in greens, browns, dark blues, etc., it is extremely easy to prepare monochrome lantern slides, which far surpass any that can be prepared by the ordinary photographic methods, for in the latter the image consists of particles of silver or other metals or pigments, whereas by the Pinatype process the image is formed of absolutely grainless and transparent dyes, and there must be, therefore, a far finer effect of transparency which, combined with the absence of any deposit in the higher lights of the picture, gives effects which are otherwise unattainable.

SEVEN-STOREY Kodak Building.—Ground for a new seven-storey building has been purchased in New York City by the Eastman Kodak Company. The new building will be located in Twenty-third Street between Seventh and Eighth avenues, and will be used altogether for warehouse purposes. Work on the new building will be started as soon as possible. At present some small buildings are located on the property, but these will be torn down without delay. The company will occupy as much of the building as it requires, and may rent some of the space. The offices of the company will not be moved from their present location in

Twenty-second Street. This will be the second large building to be started by the Eastman Kodak Company within a few weeks. At Kodak Park a new factory for the manufacture of film is now in whole course of construction. It is expected that both buildings will be completed by the early summer of next year.

ROYAL Postcards.—Princess Christian sent many of her friends some charming picture postcards conveying good wishes for Christmas and the New Year. One lot of cards consisted of beautiful three-quarter length photographs of herself, with Her Royal Highness's autograph on each.

## PICTORIAL AIM IN PHOTOGRAPHY.

A Lecture delivered by Mr. Archibald Cochrane at the third General Meeting of the Edinburgh Photographic Society for Session 1905-6

I HAVE drawn together some thoughts on a subject that must be frequently in the minds of those who are interested in the advancement of pictorial photography. Many are speculating on the tendencies of the movement, what school is most likely to "catch on." I shall, to-night, attempt to find out rather what school is most likely to "hold on." I do not urge you to follow any particular school with which you do not feel in sympathy, because its work is in vogue at the moment. Successful work is not done in this way. Rather I shall attempt to determine what, in any school, is best for us to emulate, and what influences we should resist, being guided to my conclusions by dicta that are applicable to art in general and pictorial photography in particular. To what should we bend our best energies, and in what direction should we who love the pictorial in art direct our aims.

### The Pictorial Appeal to Emotion.

We had better begin with the essentials of a picture. I take it for granted that we are all alive to the importance of pleasing line and good composition, not to mention a strong feature of photography, the charm of *chiaroscuro*, the "intercourse of light and shade." I want to go on to something higher than this. What constitutes the artistic quality which most of us seek earnestly? The Photographic Salon organised by the Linked Ring is probably the best exhibition of pictorial photography that is available for us to study, and what do we find is the qualification of admission to that important assemblage of photographic pictures. Here we have it, "Work only admitted which shows personal artistic feeling and execution." This seems a subtle rule to measure work with, yet it works well. Amongst those who have educated perception it is quite wonderful how quickly the necessary quality is discerned in a pictorial contribution. It is a puzzle to many aspiring pictorialists to know whether their work will make this appeal. Is it definable what is this artistic feeling and quality? It is not easy, as it is not easy to explain the charm or some other quality we love a picture for. Is the artistic feeling we appeal to uniform? No, not entirely, but wonderfully nearly so in those who have educated perception. (I qualify by the use of the word "educated," as those who are in a process of art development may have a less sensitive emotional nature, or may misunderstand the intent of the work they are observing.)

A picture which has artistic feeling is one that will appeal to the emotional side of our nature, and will create a feeling of loving sympathy with the work; a yielding of ourselves to its influence. The artistic achievement will be in proportion to how much we are made to feel. Do we feel with the artist and get a new standpoint of understanding? Our soul opened to sympathetic response where it had been dormant before? In this appeal to our emotions through our visual sense we seem to have more of the intellectual quality than is the case with music, where we are made to feel certain emotional experiences without being told what it is all about. You feel, in listening to the strains of a soul-stirring Largo, a sadness almost to tears; you know not why. Because of the simplicity of the emotional appeal to music many think it the purest form of art. Others again desire to have words to the music, or at any rate a descriptive programme indicated by the composer as to his emotional intention. In this case music becomes more nearly analogous to the appeal of the picture, where we generally know "what for" we feel a certain way about the work. Whilst it is a true and rich experience for humanity to have a susceptible emotional nature, still this must be balanced with reason, and held in proper proportion. We must not be over-emotional. The young art student, particularly if he go to finish in Paris, and has come under the influence of the French ateliers, often allows his emotional nature too much ascendancy. His soul is being continually swept with hurricanes. He does not talk calmly, but indulges in rhodomontades. He works at a high voltage (his best point). He comes to consider these moods as the true manifestation of the artistic soul. This passionate artist deals with Love, Hatred, Death, Blood, Passion, Poison, everything, in fact, save Piety. When a photographer comes alongside such an ardent soul, he hides his picture-making machine, and wisely refrains from indicating that he had any design on the

emotional preserves of his friends at home. If he have no desire to bring down the thunder, he can spare himself a rich emotional sensation by keeping a discreet silence. The photographer will be found plying his art later on, and we may venture to assert the claim that we can, with our pictorial work make men and women feel with emotional intensity, as deeply as can the painter, and in some cases the musician. We may produce slight things, the equivalent of the Gavotte or the Intermezzo in music, which appeal to little beyond the pleasure of the senses. But ambitious workers will one day want to produce something big that will appeal to the greater and nobler emotions.

### Feeling as a Judge of Pictorial Quality.

Now, perhaps, it is wrong of me to start on such a high platform. For, when shall we see a gallery full of photographs (or for that part of it, paintings) making an appeal to our inner nature? Probably, never! The bulk of words stops at being a correctly laid out composition and showing expert handling. We may see this kind of work, and, although thinking it all very good, yet we are untouched by it. It is possible for a pianist to be a great executant and yet not an artist, and although many are satisfied with the digital exhibition, yet it is the artistic quality that is so precious. The same with the photographer. He may be an expert technician and yet not be an artist.

Although I have stated that emotional effect is generally associated with an idea, in painting and photography, yet it is also true that the beauty of a line, which makes no intellectual appeal, may make us feel pleasure and joy. So also may colour arrangement; but the nobler emotions in graphic art seem only to be awakened when there is some intellectual suggestion.

The great judge, Feeling, presides at the bar of art, and there is little use in trying to overthrow his rulings. You listen to a song, and if you do not like it, no man need attempt to reason you into liking it (you know better than to attempt the task yourself). In the picture world it is much the same; you will not succeed in reasoning yourself into liking a picture if your feeling is against it. The dislike in the case of a picture is more intelligent than in the musical instance, as we are linked up more closely to the intellectual in our department of art. Yet feeling is the supreme judge. You feel that the modelling of a face is wrong, and you may not be able to say where, yet the feeling is justified. It may be that the planes are wrong in the tonal scheme of a picture, you may not be able to say what is amiss, still you feel that the rendering is not right, and such a feeling may generally be relied on. I have not time to go into what constitutes this feeling by which we are guided, but it may suffice if I say that it is a product from observation and stored up deductions from past experiences in the mind. When we find that our feeling is against a picture, it is not an unintelligent prejudice against the work in view, but is really the attitude of a trained emotional nature. When we feel admiration for a picture we may have this feeling without having taken thought for what we liked it. If we were to analyse the work, we should find that there was full justification for the feeling. The necessary canon of art had been attended to, and there were beautiful features so arranged that the appeal went straight to our emotional centre, the "seat of fond delight."

Now, I want for a little to consider certain features that go to build up an effective ensemble that will make a sure appeal as being an artistic work.

### Avoid the Commonplace.

Now, first of all, the subject. We are told that this may be anything "if paintable." I would recommend that in our branch of art the subject should be as important as we can find to do, so that our minds and aspirations may be lifted up continually. To lavish study and observation on an accurate representation of an unimportant subject, such as "copper stew-pans," would be a waste of our talents. The technical achievement may astonish (a cheap emotion) at the moment, by its resemblance to real stew-pans, but when all is said and done, the real culinary utensil will be as satisfactory to look at, and it also will have a gastronomical interest that

the other lacks. Subjects into which no artistic feeling can be infused should be avoided. The subject must appeal to the worker or he cannot put feeling into it. One cannot play a piece of music with artistic feeling if he is not moved by the composition which he is performing. All that can be expected of the performer (even if he be a great maestro) is, that the performance is unexceptionable as regards accuracy and technique. If the character of the subject be lofty, the pictorial worker's imagination will be fired, and his emotions touched, and in time if his rendering be successful, we will share in his experience.

The subject should show originality in choice. There is rightly high value given to this feature, as there is no over-supply of the inventor. Some do not approve of the commonplace subjects being treated by some of the men of the new school. But such objectors should remember that original work of this kind was also produced in the good old days. I have heard devotees of the Royal Photographic who date away back to the wet-plate times, and who are of a very reminiscent turn, speak with tears in their eyes of Davison's "Onion Field." No modern work seems to affect them like this.

### Portraiture.

The most important branches left for fresh and successful photographic work are portraiture and landscape. In portraiture, photography will probably reach its highest pictorial realisation. In no other class of work has the worker such opportunity, and the arrangement so much under control. There are few painters who could model a face as it is being done by the camera in skilful hands. It is said that the lens cannot see below the surface of the sitter. A painter is supposed to chronicle the inner qualities and characteristics of his sitter. This is accomplished at times, but, as a rule, the portrait painter is baffled to get correct resemblance of the outer man without attempting the interior. As I have already said, it is in this class of work that photographers will rightly take a high place. At present among us there is a tendency to run too much to one class of subject, such as the "mother and child" style of thing, which was started in the American nursery a few years ago. A worn groove should be avoided, unless one feels that he can "go one better" than anything as yet realised.

### Landscape.

For landscape work of the highest class we must get into sympathy with Nature. I sometimes think that the photographer in us is apt to kill the poet. The hunt for pictorial "bits" would appear to preclude the poetical possibilities. We have not the leisure to get into the contemplative mood of the poet. "What will compose?" is our feverish query, and it seems to occupy the mind more than any consideration of Nature's mood. We are told, "Yonder is a beautiful sunset." "Yes," and you recognise that there was a day when you admired such a sky, but now, alas! you know that it does not compose, therefore your interest in it is lukewarm. The colour may suggest to you that a tissue of that colour would be suitable for a really good sunset. I say that I think it is unfortunate if this represents a common experience. The painter is more happily circumstanced. He can give all the days of a month to study his "bit," and with so much leisure he can well spend the time to get into the spirit of the scene. One cannot rush this mood, although we must be busy when we are making records of a scene, and prosy thoughts may fill the mind, still, if we cannot at that moment, then at other times, we must make an endeavour to get into close touch with the spirit of Nature. We must be susceptible to Nature's moods before we can adequately attempt to portray them. There is certainly great difficulty in getting subjects that will compose artistically. Should he succeed in finding a well laid-out picture in nature, the expert artist-photographer may be trusted to make the most of his opportunity. If the worker knows how to manipulate his process nothing will be lost of the spirit of the scene. He will have to give up the colour, but by skilful development he will give as near as possible its equivalent tonal values. It is seldom, however, that we can put a satisfactory scenic setting before the camera, and we cannot import into the scene wholesale pictorial features in the way that Turner has embellished his canvasses. One can do something, certainly, by the use of several negatives, and combining these studies into one picture. Great knowledge is needed in this, to get the tone values into their proper relation. In all such ambitious attempts it will be necessary to employ much handwork on the negatives. This, how-

ever, should be kept down to the least possible amount, as the handwork will never rival the quality of the detail work of the negative. Some work (in keeping with the quality of the negative) can be added with tracing paper as a backing, but I am of opinion that there is a loss of quality if carried too far. Before we know it, an artificial, unreal quality will have come into the work that will be repellant to the observer.

### Figures in Landscape.

If figures are introduced into landscape they are apt to be self-conscious, and prove hurtful features in the composition. Unless the figures take their place naturally in the scene they are better omitted. There should be some motive for them being introduced. I noticed some nudes at the Paris Salon, introduced into a landscape scene, without any "motif." The realism of the rendering showed that the model was clearly embarrassed that she should have nothing to do in the field. It would not have improved matters to have pictured her pinning up a washing unless it were to show the poverty of the lady's wardrobe, and that a change was not available. If figures must be introduced then they must be engaged at something sanely appropriate.

Before passing from this head I might remark that figures should be small if the interest is centred in the landscape. If the study of the figures be of primary importance then they should be large with a landscape background. If the figures be of medium importance it will share the interest with the landscape. This makes rather a trying arrangement, and the eye is at a loss where to settle.

We cannot find chosen landscapes of beauty to our hand, it may be; but ordinary material is sometimes lifted to a state of beauty by the atmospheric conditions and the quality of the lighting. This is our chance, and the earnest worker must always be on the look-out. Do not say "We cannot get away at the moment." Fortunately we often can, as the best effects are generally at the end of the day. Broad daylight effects are seldom successful. The charm comes with the morning light, or with the even more beautiful evening rays.

### The Bane of Falsity.

We hear much about "truth to nature." Now this sometimes puzzles the worker, who thinks that his negative suffers from an overdose of stern facts in all their naked truth. Such truthful rendering of so many facts is eminently useful for a study, but these facts must be put into their relation to the picture as a whole, by sunning down, or in some other way lowering certain tones or softening focus of other parts, and thus simplifying the appeal to the eye. Yet at the same time whatever is rendered in the picture must be true to what it purports to represent. A natural object that is imperfectly represented as regards texture, modelling, or tonal value, must be repugnant to the observant eye. So that we photographers must "take heed where we stand lest we fall," by attempting modifications of our scene. We may still be true to the structural quality of our pictorial material, and be able to idealise the scene. An imaginative rendering must always be more lastingly interesting than an accurate transcription of a landscape. At the same time we must show true observation of nature's moods, an intimate understanding of all the works of nature that we may attempt to portray. In this branch of work we must strive after originality, as mentioned in the case of portraiture. There is too common a tendency to look at nature through the successful exhibitor's spectacles.

### Schools of Photography.

I should like to say something regarding the different schools of photography. The Edinburgh school has always been academic, producing good, sound, reliable work. (This is very temperate language.) Notwithstanding its attainment to good things I am of opinion that no harm would be done if more outside influence could be introduced. Some new varieties of beauty grafted on to your flourishing growth. I remember a picture shown at one of your exhibitions some years ago, which was a departure from the style of work usually shown here, but it did not create a vogue, and there were no workers influenced by its direction or tendency, as far as I know, and yet I think it was one of the finest pictures I have seen on your walls, as far as my knowledge of your exhibitions goes. This medalled picture was of a "Man Drinking." The focus was pretty soft, if I remember aright. It was, as I have said, a very new style of thing in your exhibition, but this successful example did not alter the direction of your aim to any appreciable degree. You do-

not experiment readily. You are, no doubt, satisfied with the solid reputation which you have built up for your society, and you naturally do not wish to jeopardise your position by any risky departures from the traditional class of picture.

It would interest you to see the material that a leading American worker utilised for picture making when in your picturesque capital. These pictures were not always captivating, but the freshness of the standpoint was a revelation. There is an abundance of material down in some of these old lanes and narrow thoroughfares that would make delightful gum pictures with the quality of a rich etching.

A recent etching, shown in London, was of "Ayr Prison." Here we have a suggestion for some Edinburgh worker. He might show his intimate knowledge in a realistic rendition of "Calton Jail."

#### American Eccentrics.

Seeing that we have made an allusion to American work, we may as well proceed to consider this school, which is as far removed from the Edinburgh methods as are the countries geographically. The most striking feature of Transatlantic work is its freshness of outlook. Things that have never been done into pictures before are now made to do duty, and are worked up assiduously. In this country we did not utilise such material, as we did not see that a picture could be made of it, and many of us do not see that a picture has been made of it. Many of the things put forward by the American school would give one the impression that pictorial subjects were exhausted, and that they must use commonplace material with a big dash of the personal in it to make things hum. Often this style of thing succeeds on account of the daring exhibited by the worker in making the attempt. If the thing is done with the necessary degree of courage it will always be sure of attracting attention at exhibitions. This class of work is put forward with cheek, and this is often the only Whistlerian attribute it possesses.

But whilst there is much eccentricity that we do not approve of yet there is a large amount of work being produced on the other side that shows a striking amount of insight into subjects that will yield them pictorial material. These American workers make us look again at ordinary things, and we find that we had overlooked something that was quite precious. The leading American workers show us that they have gripped the great pictorial truths, and they are revealing to us how they can make them serve their purpose. Although I am opposed to much of the American pictorial produce, still I readily admit that the pictures produced by photography which have made the highest appeal to the spiritual and emotional in us have been produced by Americans.

#### A "Rouged Corpse."

The German school cannot, I think, show us any lead that would be of any advantage for us to follow. They have carried colour printing in gum a considerable distance, but these essays have no æsthetic value. The gradations are clumsy, and the colours administered in large, even masses of half-tone. It would be better to learn to paint the picture from the start. One could soon reach the point that these coloured gums would occupy in the painting world.

## FOREIGN NOTES AND NEWS.

### A New Liquid Lens.

A FLUID lens has been recently patented in Germany under the name of "ophthalmochromat," which consists of two thin glass discs cemented together and filled with a fluid. Some extravagant claims have been made for this. As the thickness is only a few millimetres, very little light is absorbed, and it is therefore more rapid than an anastigmat working at the same aperture. The chromatic correction is said to be perfect, and, further, it possesses such great depth of focus that every object from two to three yards to infinity are simultaneously sharp. Even the colour rendering is better with these lenses, and orthochromatic plates are no longer necessary. Thus the puffs; but the cold facts are not so rosy. It turns out to be nothing more than a biconvex fluid lens, and possesses all the faults of such a form, namely curvature of the field, non-achromatism, coma, distortion, etc. With full aperture F/9 the whole image is fuzzy, and with smaller stops the definition is no better than with an ordinary spectacle lens. Sic transit gloria—advertisements.

The French have produced some striking colour works in multiple colour gum very much resembling pastel. These, although carefully done, have no colour quality so far, judged from a painter's standpoint. Something more may be done by this particular method, but by the time it is satisfactory the process will not be essentially different from painting.

Some of the work at the Salon this year had tinting on some of the lights, such as touches of yellow. I do not know how it would appear to a painter, but to me as a photographer it suggested chemical dissolution. Any one who had not experienced a chemical discoloration might not have this feeling. I should not like to say that this colouring habit will not go further; I fear that it will, now that the lead has been set by illustrious workers. That which I have seen with tinting has not favourably impressed me. But it is within the bounds of possibility that complete photographs may be coloured by hand some day, and it need not necessarily be bad art. That would depend on how it was executed, well or ill done. An art critic has likened a coloured photograph to a "rouged corpse." This is a wee bit hard, but probably it would be found to be near the truth as regards the bulk of such productions.

### The Printing Process.

Perhaps I should say a word on process before closing. By what printing medium shall we express ourselves? Our aim might be right, and also our achievement as regards the negative and the preparation of it for printing, and yet fail to get what we want in the print. The better way is for every capable worker to judge for himself. He should print from a good negative a number of copies in the different available permanent processes, and choose the most artistic by the results. The carbon process has hitherto given me the results I desired. Gum has not tempted me up till now. I did not succeed in getting as satisfactory prints by gum as I had by the process I already practised. Gum was in my hands too erratic. My experience was something like that of a regular exhibitor at the Salon. I asked him why he had not sent a certain subject in gum. His answer was delightfully candid, "I had not time."

I am taking a new interest in gum since some paper of a Scotch make fell into my hands. I did not believe that it was possible to get such uniform results by this process, and it was a pleasant surprise to me to find so much control possible, and yet have a straight out print if such was desired. Although wrong in principle yet there seems to be a working point where the difficulties can be got over and a compromise reached if the coating be thin enough. As regards the recent London exhibitions, I did not find that gum was advancing, either in popularity or in performance, as might have been anticipated, but I am of opinion that recent developments are likely to bring this process into much greater favour. Now, in conclusion, I would urge that the great thing for us as pictorial workers is, that our powers of appreciation of what is artistic be developed to the highest point, so that we may be quick to seize fleeting opportunity. Art is long, but the time for practice is brief.

### Metallic Emanations.

In the "Phys. Zeitschrift" Strintz states that magnesium, aluminium, zinc, and cadmium, which are electro-positive, will, when polished, act on paper soaked in potassium iodide, and also on dry plates, but the latter are less sensitive than the former, and therefore a longer time is required to form a latent image. In twenty-four hours polished strips of magnesium give a very vigorous image, aluminium a vigorous one, but zinc a faint one, and cadmium a very faint one. The magnetic metals, cobalt, nickel, and iron will also blacken silver salts, but a prolonged contact is necessary. The action decreases considerably with the increase of the distance of the metal from the film; the images are broadened, as though the air had some dispersive effect, and the edges become indistinct. ●

### A Projection Anastigmat.

The optical firm of Rodenstock, of Munich, have introduced a new anastigmat for projection purposes, which consists of four uncemented lenses. It is stated to possess a very flat field and to

be free from distortion and all other aberrations, and is suitable, therefore, for photographic work. Its aperture is F/3. 8.

### Stable Colours for Three-colour Prints.

M. Pacini, of Marseilles, after experiments, recommends the use of picric acid, carmine, and Prussian blue for the pigments for three-colour prints prepared with bichromated gelatine, the idea being that these are stable in light and not liable, like aniline stains, to fade. Unfortunately, gelatine impregnated with picric acid darkens on exposure to light, as was pointed out by Burton many years ago. The carmine is used in an alkaline solution, and the Prussian blue is formed *in situ* by immersing the gelatine relief in the ordinary sensitising solution as used for the ferro-prussiate paper. It is then dried, exposed to light, and developed in water as usual.

### Developing P.O.P.

In the current number of "Das Bild" Drs. Knopp and Biltz give the following table of developers and tones obtained therewith on faintly-printed P.O.P. It will at once recall to our readers' minds the table by Schmidt which appeared in our issue for August 18, 1905, p. 646:—

Developer.	Acetone	Chloro	Silver	Potash	Bichro-	Chlorine	Various.	Approximate Colour of Fixed Print.
	Drops	Drops	Drops	Drops	mate 120	Alum 120		
Gallic Acid 15gms	—	—	—	—	—	—	—	Brown
Sodium Acetate } 30 "	—	—	—	—	—	—	—	Green
Water 1000 ccs.	4-10	—	—	—	—	—	—	Green
Con. sol. of Gum Arabic 60 c.c.	—	—	—	—	—	—	—	
Meto 2 gms.	20	10	—	—	—	—	—	Photo. Brown
Water 1000 c.c.	—	15	—	—	—	—	—	Gold Tone
	—	—	—	—	—	—	Sod. Sulphite 1-10, 10 drops	Carmine
	—	—	—	—	—	—	Tartaric Acid 1-4, 5-10 drops	Yellowish Brown
Hydroquinone 10 gms.	10	—	—	—	—	—	—	Yellowish Brown
Water 1000 c.c.	—	—	.5	—	—	—	Gum Solution 10 c.c.s.	Photo. Brown
	—	—	—	—	—	—	—	Red Brick
Hydroquinone Developer 20 c.c.	—	—	5	—	—	—	Gum Solution 10 c.c.s.	Gold Tone

Water 1000 c.c.	—	1 c.c.	—	2	—	—	—	Greenish Brown
	—	1 c.c.	—	2	—	—	—	Olive
	—	—	—	—	—	—	Glacial Acetic Acid 1 c.c.	Chocolate Brown
	—	—	—	—	—	—	—	Dark Reddish Brown

### The Lanternist's Problems.

The following very simple statements of the calculations required to find the necessary distances in optical projection and enlarging are given by M. Niewenglowski in the "Photo-Revue":—

The accompanying diagram shows the relative positions of the image *a b*, which is to be projected and enlarged, the lens *O* and the enlarged image *A B* on the screen.

We will represent the necessary measurements which must be taken into consideration by the following letters, and all measurements must be in the same unit, inches or feet: *f* = the focus *O F*, of the lens *O*; *i* = one of the dimensions of the image; *I* = the corresponding dimension of the projection; *d* = the distance of the image *a b* from the centre of the diaphragm; *D* = the distance of the enlarged image from the same point; *a* = the magnification.

Then if an image 3 × 3 is to be projected to 2 × 2 yards, the magnification is  $a = \frac{72}{3} = 24$  or generally  $a = \frac{I}{i}$ .

A consideration of the like triangles *O a b*, *O A B*, shows that *I* and *i* and *D* and *d* are proportional, so that we may write  $a = \frac{I}{i} = \frac{D}{d}$

From this it is very easy to determine with quite sufficient accuracy the focus of lens that is used. On a spoiled lantern slide draw two diagonals, intersecting one another at the centre, using a needle or the point of a penknife. At equal distances from the centre draw two lines, exactly parallel, and a given distance apart, say 1 inch. Then project on the screen and focus sharply, and measure on the screen the distance between the two lines, and find the magnification. Then, without shifting the lantern or screen,

measure carefully the distance between the screen and lantern slide, and this is *D + d*; then the focus is easily found by the formula

$$f = \frac{a(D + d)}{(a + 1)^2} \quad \text{or put into words: Multiply the magnification}$$

by the distance between the screen and slide; add 1 to the magnification, and square the result; divide the first by the second quantity, and the result will be the focus: supposing the magnification to be 15 and the distance  $D + d = 128$  inches, then  $f = \frac{15 \times 128}{16 \times 16} = 7.5$  inches

To find what should be the focus of a lens to give a given-sized image in a room of given length, we use the formula  $f = \frac{D}{a + 1}$

if we assume the room to be 33 feet long, and allow 3 feet for working the lantern in, and that the slide is to be shown on 6-foot screen, we get  $f = \frac{360}{24 + 1} = 14.4$  inches.

Supposing we have a lens of known focus, and wish to know what will be the size of the projected image in a room of given size, or, in other words, what is to be the size of the screen, we use the formula  $a = \frac{D - f}{f}$ . If we assume the focus of the

lens to be 10 inches and the length of the room 40 feet, then we have  $a = \frac{480 - 10}{10} = 47$  inches, and if the slide is 3 inches, then  $3 \times 47 = 141$  inches, or practically 12 feet, the size of the screen. Practically  $I = a i$ , that is multiply the size of the slide by the magnification.

Inversely it is easy to calculate what should be the size of a slide, so that under the above circumstances the enlarged image shall occupy the whole of the screen, then  $i = \frac{I}{a}$ .

The last problem that one may meet with is: at what distance from the screen must the lantern be placed, when the focus of the lens is known, with a given-sized slide and a given-sized screen. As an example, if the screen be 6ft. square and the slide 3 × 3 inches, the lens has a focus of 9 inches. Then first finding the magnification  $72 \div 3 = 24$ , then  $D = (a + 1) f$ , we get  $D = (24 + 1) 9 = 225$  inches or practically 19 feet.

## THE MUDDLE OF THE COPYRIGHT.

VARIED comments have lately appeared in the newspapers regarding a case of interest to photographers and publishers, which came up in a New York police court.

As stated by a writer in the "American Amateur Photographer," it appears that William G. Gray, a photographic printer, was arrested because he had sold photographs of "The Sowers," by Millet, which is the property of George Vanderbilt, but which is on exhibition at the Metropolitan Museum of Art. The magistrate discharged Gray; but he advised the complainant, who had Mr. Vanderbilt's permission to photograph the picture and sell copies, to test his rights in the civil courts.

Merrill and Baker, publishers, engaged William A. Cooper, a photographer, to reproduce for them pictures in the galleries of George Vanderbilt and others. Photogravure copies of the best paintings in these collections were to be embodied in a work that was to sell at 1,000 dollars a copy, limited to fifteen copies. Cooper was to own the negatives, but agreed to make no copies from them unless at the request of Merrill and Baker.

Cooper, when he caused Gray's arrest, alleged that he had engaged Gray to make carbon prints from the negatives, and that Gray knew of the agreement with Merrill and Baker, and himself agreed to make no prints other than those required by Cooper.

It was specifically charged that Gray retained the carbon prints and negatives of the Millet picture and sold them to Hegger, of Fifth Avenue, and other art dealers, and sent the negatives abroad.

Cooper alleged that the value of the pictures said to have been disposed of was 4,000 dollars.

It is difficult to say what amounts to a publication of a work of art, and each case depends entirely upon the facts. The sale of a picture is not a publication of it. The publication of a wood engraving of a painting in a magazine, with an article describing the painting, is not a publication of the painting, for to constitute a publication there must be publication of the thing itself, and not a

copy, so the publication of a cast is not the publication of the statuette from which the cast is taken.

The starting point here is the intention of a publishing firm, Merrill and Baker, to produce a work containing a series of photogravure copies of certain paintings, the property of George Vanderbilt and others, limited to fifteen copies and to cost 1,000 dollars each, the presumption being that the owners of the paintings were also the owners of the copyright thereof.

The first step of the progress seems to have been that the publishers, not being photographers, employed a W. A. Cooper to make the negatives in the private or public galleries where they were, and their right to do so is evidently undisputed. Here, however, the publishers made an inapprehensible mistake; the negatives were to be the property of Cooper, although he was to print from them only at the order of his employers, the publishers. Now, it seems that Cooper was not himself a printer, and employed a W. G. Gray to make the prints; and here begins the mystery. Cooper was employed to make negatives for the production of the photogravures for the 1,000 dollar book, and was only to print from them on the order of his employers; yet he employs Gray to make carbon prints from them. It is just possible that there is something not recorded in the extract here reproduced that might throw light on the carbon question, but there was evidently no excuse for Gray, as is alleged, retaining negatives and making and selling carbon copies from them, as seems to have been proved, and yet he was discharged, the magistrate saying that it was a serious question whether Cooper or Vanderbilt were injured.

A more serious question, apparently, is the injury done to the publishers. And very little thinking is needed to show that a book, the edition of which was limited to fifteen copies, and the value of which was 1,000 dollars per copy, was dependent on its illustrations. It would be very much handicapped by sales of carbon copies of those illustrations for, practically speaking, an old song.

## ART IN THE RECEPTION ROOM.\*

It seems to be the fashion now among photographers to decorate the reception room of their studios with oil paintings, to the total exclusion of photographs, which are kept in cabinets or sample cases. When the art display comprises works of considerable value, and evidences of the proprietor's true vocation are lacking, what wonder if a stranger mistakes the place for the office of a regular picture dealer. Such an error might flatter the vanity of the photographer desiring to abrogate to himself the airs of an art connoisseur; but is it consistent? Is it honest? It has been the sincere belief of many successful practitioners that to screen the character of the photographic studio, often mistaken by timorous persons for a real "operating room," is excellent diplomacy, and the substitution for the conventional coloured enlargement with its gorgeous gold frame, or the customary array of prints in variegated enclosures, oil paintings, water-colours, statuary or other evidences of a refined and cultivated taste, impart to the establishment a distinctly artistic atmosphere. In many cases where the photographer has sent forth work of a high order of merit, the end seems to have justified the means, and his patrons are impressed with the idea that he is truly an artist.

It cannot be denied that an impressive art display enables the artist photographer to exert an educational influence over those of his patrons who have but a limited idea of artistic taste or fitness and to instil in their minds maybe the first principles of what constitutes a beautiful and appropriate likeness. It thus serves a useful purpose. When, however, the photographer is deficient in knowledge of art, and knows not how to produce a likeness conformable to well-known art principles, he assumes a false and embarrassing

position in making an ostentatious display of valuable paintings in his studio, and, unable to practise what he pretends to preach, he will reap only failure and humiliation. A distinguished American photographer, whose professional quarters are spacious and commodious, devotes one large and well-lighted room to the uses of a picture gallery, where at all times may be seen examples of the work of eminent American portrait painters, who do not need to be urged to exhibit here. Not only does this afford a convenient opportunity for artists of note to display their work, often with pecuniary benefit to themselves, but it serves to entertain and educate patrons of the establishment while waiting for the appointed sitting. Incidentally it forms an ideal preparation for the frequently dreaded ordeal in the studio and, in this case, a valuable asset of the establishment, besides showing how art and photography can be made to help each other.

The reception room, one of liberal dimensions, contains a limited number of photographs, framed in dark mouldings, which illustrate the artist's scope and versatility. A grand piano, the usual amount of furniture, including cabinets holding specimen prints, several large plants, Oriental weapons, bronzes, and bric-à-brac, all in subdued tones and excellent taste, serve to produce a rich and harmonious effect, but not a single picture in colour is to be seen. The proprietor is a talented musician and a man of liberal education, having also travelled considerably in Europe, the artistic appointments of his establishment are singularly appropriate. Like Pelscheid, Duehrkoop and Van der Weyde, who are men of culture and erudition, this American photographer enjoys the friendship of painters, musicians, and men of letters, and on occasions his reception room becomes a *salle de musique*, where the genius of music is supreme.

\* From "The Photo Era."

## MACHINE PRINTING OF DRAWINGS AND FILM NEGATIVES.

At a recent meeting of the New York Camera Club, a demonstration was given by Mr. F. C. Beach of a simple apparatus for the rapid duplication of plans and tracings, or for printing from flexible negatives. For the text of the report and the illustrations of the machine we are indebted to our contemporary, the "American Amateur Photographer."

The apparatus is designed to produce duplicates of drawings principally, which will be reversed as to colour but positive as to letters, figures, writings, etc., without the use of a printing frame, and with greater facility. It is also adapted to make positive prints from film or flexible negatives.

As will be noticed in the accompanying illustration, the machine consists mainly of two rollers about three inches in diameter, similar to the rolls in an ordinary clothes wringer, mounted one above the other; the upper one is solid, covered with soft felting material, and runs in slotted bearings at each end, having pressure springs above to exert pressure on the lower roll. This latter is more complicated, but runs in solid bearings. It consists of a glass cylinder about one-eighth of an inch thick, having a metal plug in one end with suitable ventilation openings, and a shaft to fit in a bearing in the supporting frame. The other end of the glass roll is open and is held in position by outside roller bearings, supported in the frame. On the interior of the transparent roll is a shade held stationary, extending the full length of the roll, which has a slot in its upper part directly under the contact point of the two rolls. Supported upon another removable frame is an incandescent candle-shaped electric light bulb made long enough to equally illuminate the slot in the shade within the glass

varied by inserting resistance in the motor circuit to make the motor rotate faster or slower if the drawing is thin or thicker.

In the case of film negatives, the intensity of the light may be reduced by interposing between the lower glass light roll and the negative one or two sheets of translucent celluloid. When the right thickness has been determined by experiment, duplicate prints may be made with certainty. Mr. Beach operated the machine from an ordinary electric light bulb socket before the members and exhibited

Apparatus for Making Bromide Prints Without a Printing Frame.

cylinder, or, in other words, to illuminate only the section of the drawing or film at the actual point of contact of the two rolls. The electric lamp is inserted at the open end of the glass roll. Gears at one end of the rolls cause the latter to rotate with equal speed. In front and behind the rolls are platforms arranged for feeding in the drawing as the rolls are rotated. It is highly essential in this machine that the rolls shall revolve with a continuous, steady, music-box-like motion, in order that the light may act equally upon the whole sensitive surface. An uneven movement will show in the form of lines across the print. It was found that a small electric motor produced the right effect, although the machine could be operated as well by a spring or weight suitably geared up. It will be observed the shaft of the small motor (similar to an electric fan motor) attached to one side of the platform has a spiral worm screw on its end which engages a gear wheel; from this gear the speed of rotation is still reduced by other interchangeable intermediate gears, until the right degree of movement is ascertained for a given thickness of drawing or negative to be run through. The diagram shows plainly the principle of the apparatus.

In operation the sheet of drawing is laid upon the platform, then over it is laid a sheet of slow bromide paper with the sensitive side upward, the motor is started, and the drawing and sensitive sheet are pushed or fed to the two rolls. The time of exposure, or of the passage of the drawing through, is about ten seconds. The exposed sheet is then developed and duplicates are obtained by simply repeating the operation, all in a dark room. The time of exposure can be

duplicate prints of a drawing and film negative which he had made shortly before the meeting. He explained that it was possible to photograph through letters or documents of any kind in this way and secure fac-simile copies showing the various water-marks and other markings in the paper of the original as wet. By exposing through the back of the sensitive sheet the print shows the writing as white reading the right way, while the ground is black on the reverse in colour of the original.

### STEREOSCOPIC PORTRAITS.

(Received too late for the "Almanac.")

THE study of optics, and both the working and playing with optical instruments, has been with me the hobby of a lifetime. As a lad, though, I took very little stock in the stereoscope, as such; I enjoyed the big pile of views, but looked at them with one eye. Plenty of people do so, but whether from a similar cause I know not.

My own eyes are very unequal, and in my early youth I was markedly affected with what the doctors call strabismus—polite, but unlearned people call squint, and my very unpolite and still less learned school friends called by a very vulgar name indeed. I can see stereoscopically, but the way I have to accommodate my eyes to the instrument instead of vice versa annoys me. Many times have I been struck by a passage in "Kingsley's 'Two Years Ago,'" published early in 1857, suggesting the use of the stereoscope in portraiture. The contention in the passage referred to, that the use of the stereoscope would avoid many of the exaggerations of "the one-eyed cyclops staring at his petrified brother cyclops" depends on the focus of the twin lens system; if too short the exaggeration would be liable to aggravation. That stereoscopic portraiture might eliminate or destroy minor blemishes is possible. Looking through the literature of the subject, I find that Claudet, that many-sided genius of the early days of photographic art, actually did such work, the price he charged being one guinea a copy. Luck man! But then Claudet was Claudet, and it is not to be supposed that he trusted the mounting of such work to his errand boy or even to the lady of the reception-room.

If this should meet the eye of any photographer, professional or otherwise, or even the eye of one who is no photographer at all, and a stereoscopic portrait of himself or friend is required, he may

obtain more than one copy for very much less than a guinea, as follows:—

Patronise the lowly (or is it not more often lofty?) den of the postage stamp, gem, or Victoria artist, merely stipulating that you want the goods unmounted and uncut; you will probably find him not too proud to accept the same price for the lesser amount of work, and he will be more anxious to please. Do the mounting yourself, carefully laying down the prints at the regulation distance apart, taking care to reverse right for left in the case of silver prints; with ferrotypes this is not necessary. There is a possibility of variety about the whole business that should lend the experiment an additional charm. With three rows of three prints taken with a nine-eyed Argus—I mean camera—you could take two prints wide apart, or two prints close together, giving your face just as much solidity as you pleased; you could mount a pair wrongsidely and see yourself hollow-faced; you could mount a pair taken slantingly and look at yourself cornerwise. But this is getting frivolous—fortunately it will be published about Christmas time.

C. RAY WOODS.

## Photo-Mechanical Notes.

### The Zander Complementary Colour Reproduction Process.

THE patent specification of the process, a description of which appeared in the last issue of the BRITISH JOURNAL, has now been published (No. 27,023, 1905), and some extracts therefrom will amplify what has already been said and claimed by Mr. Zander in "Penrose's Pictorial Annual." The four printing colours are magenta, red, lemon yellow, emerald green, and ultramarine blue. These hues may be departed from to some extent without detrimentally affecting the results obtained to any great extent, and such departure may be necessary or advisable in certain circumstances, as for example, when it is desired to use more permanent pigments as reproduction colours than those which most nearly yield the four fundamental hues described. Thus, one or more of the following substitutions may be made: carmine for magenta, sulphur yellow for lemon yellow, peacock green for emerald green, violet blue for ultramarine. At the same time it is to be noted that the hues selected respectively for the red and green pair and for the yellow and blue pair should be as nearly as possible complementary to each other.

The allowable variation in the four fundamental colours and the spectral position of the preferred colours are best expressed by reference to their wave-lengths. Thus for the yellow may be used any or all of the hues having wave-lengths between 6,000 and 5,600; for green, any or all of the hues having wave-lengths between 5,600 and 5,000; for blue, any or all of the hues having wave-lengths between 4,900 and 4,200; while the limits of the red are defined by the complementary colour of any or all of the hues of spectrum green between wave-lengths 5,500 and 5,000. The preferred hues may similarly be defined to those corresponding to wave-lengths 5,890 (about D line), 5,220 (about  $E\frac{1}{2}$  b) and 4,580 (about  $F\frac{1}{2}$  G), together with the colour complementary to that of wave-length 5,220.

In carrying the colour scheme into practical effect the requisite photographic colour-records or negatives are made by using a combination of suitable colour-sensitive photographic plates and selective colour filters, each of which, roughly speaking, should pass all the colours of the spectrum with the exception of the respective reproduction colour, the latter being represented in the negative or film as more or less clear glass or film according to the density of that particular colour in the original, whereby are produced monochromatic records in hues respectively approximating to the complementaries of the four proposed reproduction colours. From these negative colour records, printing positives (blocks, plates, and the like suitable for the various printing processes) or transparencies are made for reproduction respectively in their proper colour.

It is advisable in these colour records that there should be overlapping in the green and red records in the region both of the D and of the G lines, and in the yellow and blue records in the region of

the lines E and b. These overlappings, the extent of which is discretionary and may be determined empirically, produce corresponding gaps at D, G, and E to b in the positives, whereby the production of the yellow, spectrum green and blue respectively may be effected.

### Paper Negatives for Poster Collotypes.

The operation of reversing, by stripping, a negative intended for the production of a collotype printing plate is advanced as unnecessary by a German worker, Carl Schaack, of Parkstrasse, Treptow, Germany, by whom has been patented the use of a paper negative for collotype work. The patent specification (No. 11,239, 1905), sets forth the alleged advantages of the flexible support, not only in regard to reversibility, but as facilitating retouching and preparation for printing. The granularity of the paper negative is no found a drawback in its use for poster work. The paper-negative can be freely retouched to an unlimited extent not only for "lights" but also for "shadows" by use of rubber, pencil, brush, knife, and the like and in this respect it far exceeds films. With regard to dry-plate films, it is mentioned that black spots, lines, points, and the like, which are unavoidable in enlargements, since they are due to blemishes in the original, can only be retouched incompletely and with great difficulty, since one is forced to scrape with a knife through the hard layer which appears as it is polished; this is a very difficult process, which requires exceptional skill on the part of the operator, and nevertheless does not always succeed so completely that subsequent treatment of each separate print can be dispensed with, a very tedious operation with large issues. Owing to their cheapness, paper-negatives allow of making small issues even of the largest sizes, which is of the greatest importance in competition with other processes. They combine with small weight, easy manipulation in technical work, and allow of adding text and decoration to the pictures.

### Sweating in Process Cameras.

In the current issue of the "Zeitschrift für Reproduktions-Technik," appears a leader upon the above subject, and it is pointed out that the sweating or dewing of the cross-lined screen is extremely likely to occur in cold weather, when wet collodion plates are used, and, that as it may disappear during exposure, its effects may be unrecognised, for they would principally be felt in the "flashing," and therefore would chiefly affect the shadow dot. The cause of this trouble is, of course, that the screen and the inside of the cameras are colder than the dark slide and sensitive plate. The remedy then is obvious, the inside of the camera must be warmed. The methods suggested for this are either to introduce into the camera a copper wire of about 1 in. thickness and 8 in. to 10 in. in length, and heat the protruding end, or to utilise the well-known foot-warmer principle; that is to say, to arrange for the insertion of a copper vessel filled with super-saturated solution of sodium acetate, which can be heated by placing in a boiling-water bath. As is well known, this last thermal box will give out heat for many hours.

### Applications for Patents.

The following applications for patent were made last week:—By Florence Prout Rouse, 18, Chalk Hill, London Road, New Bushey, Herts. An improved method of preparing photographic prints, for reproduction, in the manufacture of pictorial printing blocks (No. 26,568).

Improvements in process blocks.—William Francis Cooper, 12, Southampton Buildings, Chancery Lane, London. (Nos. 26,715 and 26,716.)

THE United Stereoscopic Society have recently held a competition of stereoscopic slides. The judging was carried out by members of the society (by form of vote). The following is the list of awards:—Silver medal, H. Bradshaw, "Portrait of a girl;" bronze medal, Victor Selb, "Florentine Minstrels;" highly com., F. Low, "The Climbers;" bronze medal, A. J. Snow, "A November Morning;" bronze medal, J. Cole, "In ye Old Monks' Days;" highly com., Victor Selb, "Palace," Paris. Officers of the Society:—President, Theodore Brown; vice-president, Victor Selb. Committee: Messrs. J. C. Dancer, E. Turner, J. Cole, and W. Pugsley. Hon. Secretary, A. J. Snow, 74, Lloyd Road, Walthamstow, E.

## Exhibition.

### WISHAW ARTS AND CRAFTS.

THE annual arts and crafts exhibition promoted by the Wishaw Photographic Association was opened on Saturday last December 30. The following awards in the open classes were made by the judge, Mr. Archibald Cochrane:—Portraiture or Figure Studies—Bronze plaques: A. H. Allan, Edinburgh; Dan Dunlop, Motherwell. Bronze medals: A. H. Allan (debarred), A. W. Hill, Shotts. Landscape, Seascape, or River Scenery—Bronze plaque: Fred Judge, Hastings. Bronze medals: A. W. Hill, T. Jackson, Leeds; R. M. Readdie, Edinburgh. Flowers, Fruit, or Still Life—Bronze plaque: E. Seymour, Herts. Bronze medal: Dan Dunlop, Motherwell. Architecture—Bronze plaque: S. G. Kimber, Southampton. Bronze medal: T. R. Somerford, Brixton. Any subject (confined to exhibitors who have never received an award in open competition)—Bronze medals: Miss Sylvia Cardwell, Eastbourne; R. Sneddon, Wishaw; Arthur Neilson, Partick. Lantern Slides—Bronze plaque: Fred Judge, Hastings. Bronze medals: G. J. T. Walford, Essex; H. W. Dick, Manchester. Any subject (confined to Federation Association)—Bronze plaque: N. S. M'Murtrie, Wishaw. Bronze medals: G. L. A. Blair, Paisley; A. W. Hill, Shotts; Robert Ure, Glasgow.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."*

The following applications for patents were made between December 18 and 23:—

**LANTERN-SLIDE CASE.**—No. 26,310. Improvements in cases for lantern slides. William and Henry Hudson, Tower Chambers, Halifax.

**CINEMATOGRAPH.**—No. 26,440. Method of and means for starting a phonograph or cinematograph in reproducing animated pictures accompanying an audible entertainment. Wallace Cranston, Fairweather, 65, Chancery Lane, London.

**COPYING MACHINE.**—No. 26,612. Improvements in photographic printing or copying machine. Otto Lunenkampf, 31, Bedford Street, Strand, London.

**NEGATIVE WIPER.**—No. 26,621. A wiper or pad for removing or preventing the formation of air bubbles in the development of photographic negatives and bromide prints. William Pomfret Burra, 53, Chancery Lane, London.

**FLAT FILMS.**—No. 26,708. Means for containing photographic plates or flat films and for operating same in cameras. Thomas Baker, 46, Lincoln's Inn Fields, London.

**PRINTING APPARATUS.**—No. 26,740. Improvements in photographic printing apparatus. William Mycock, 17, St. Ann's Square, Manchester.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**DEVELOPER.** No. 9,116, 1905. The invention consists in the addition to a developer, which can be used with sodium sulphite alone, of a salt of chromium, such as chromic chloride, chrome alum, etc., the function of which is to permit of the warming of the developer to 85 to 95 deg. without softening the gelatine on the plate. The following are two examples of a developer made up in this way:—1. A mixture of 2 parts of "amidol" (meta-diamidophenol) with 3 parts of chromic chloride is made by dissolving this mixture, together with 6 parts of anhydrous sodium sulphite, in 300-400 parts of water. The clear solution will develop a normally exposed plate clearly and strongly within about six minutes without damaging the coating on the plate; or, if the developing is carried out at 85 to 95 deg. F., the operation occupies only about three minutes. After the developing process is finished the plate is washed with water whose temperature is 105 deg. to 140 deg. Fahr.

For fixing the developed plate there must be used, for instance, a fixing bath made by dissolving 2 parts of crystallised sodium hyposulphite together with  $\frac{1}{2}$  part of potassium metabisulphite in about 16 parts of water. This fixing bath is applied to the developed plate in the usual manner; the fixing operation being finished, the plate is washed with water of a temperature of 105 deg. to 140 deg. Fahr., and then dried at about 176 deg. Fahr. Thus the production of a finished negative from the beginning of the developing process occupies only thirty to forty minutes.

2. A developing bath is prepared from one part of "amidol" (meta-diamidophenol), 3 parts of chrome alum, 3 parts of anhydrous sulphite, and 150 to 200 parts of water. This bath is applied to the exposed plate in the usual manner. The development being finished, the plate is washed with water the temperature of which is 105 deg. to 140 deg. Fahr., and then fixed in accordance with the method given in Example 1. Washing and drying after fixing are also to be conducted as in Example 1.

In this case the negative obtained is likewise well-shaded and with strong contrasts. C. D. Abel (for the Actien Gesellschaft für Anilin Fabrikation, Berlin).

**DEVELOPING BOX.**—No. 16,576, 1905. The claims are for a tank (for development of plates placed in vertical grooves), which is provided with two sliding covers, by means of which plates are introduced into the tank from a light-tight case, e.g., a dark slide. The figure represents the body portion of the tank, which is provided at each side with slide-ways or guides 4 arranged to receive the edges of the plates and to hold them apart from each other, but sufficiently close together to practically utilise the entire interior area. Upon the bottom of the tank is placed a layer of rubber, felt, or other suitable

cushioning material adapted to provide a soft bearing for the edges of the plates, the tank being preferably composed of thin sheet metal.

Mounted upon the top of the tank between enclosing flanges or guides 6 are the sliding covers 7, 8, both being arranged to slide longitudinally, either together or independently of each other along the full length of the apparatus. The under one of these covers rests upon a strip 9 of soft bearing material adapted to provide a cushion and to make a binding fit with the cover slides 7 and 8, so that when inserted they fit snugly within their slide-ways formed by bearings 9 and flanges 6.

For the purpose of ensuring a tight fit the slides or covers 7, 8 are preferably slightly tapered, as shown in the figure, so that when drawn apart they will be comparatively free to move, but when adjusted to the closing position shown in the figure, or when entirely closed, they will make a snug, tight fit in their slide-ways, positively excluding the light, and also making a fluid-tight joint.

The upper one of such slides 8 is provided with an opening 11 and with an inner upwardly-extending shell 12, and a surrounding outer upwardly-extending shell 13. The purpose of these shells is to receive a photographic plate 14 within the inner shell 12, and its surrounding envelope 15 (encasing the plate) between the outer walls of shell 12 and inner walls of shell 13. The object of this construction is that the plate and its enclosing envelope may make a light-proof engagement with

the inner and outer shells, before the slides 7 and 8 are drawn apart for the purpose of dropping the plate into the tank. Jesse Dougherty Lyon, Room 2,024, Farmer's Bank Building, Pittsburg, U.S.A.

**CATALYTIC PRINTING.**—No. 20,372, 1905. The patent specifies a method of treating negatives or positives, which are to be copied by a catalytic process, with substances to modify the action of the negative or positive on the catalytic agent. For example, when a normal silver negative is converted into a platinum negative or a manganese dioxide negative or otherwise treated to serve as a catalytic negative, the pictures reproduced therefrom are frequently too hard, that is to say, the fine half-tones do not appear.

This objection is now overcome by treating the catalysing original with substances which diminish its effect on the substance which is to be modified by catalysis. From the original thus treated there may be obtained prints according to the method in question which are free from the above objection.

The invention consists, therefore, in diminishing the catalysing effect of the original according to the necessity of each case. As particularly useful, the following materials and method of applying them may be cited:—1. A platinum negative is bathed with a solution of 0.1 gram of thio-urea or of 0.2 gram of thio-sinamine or of 20 drops of a saturated aqueous solution of sulphurous acid, in 100 grams of a mixture of 4 parts of alcohol and 1 part of water. The catalysing effect of the negative is thus so strongly reduced that a soft positive may be obtained therewith. 2. A manganese negative is similarly treated with a mixture of 4 parts of alcohol and 1 part of water containing 0.1 per cent of thio-urea. The action is the same. Neue Photographische Gesellschaft, 27, Siemensstrasse, Steglitz, Berlin.

## New Books.

"The Science Year Book, 1906." London: King, Sell, and Olding, 5s.

The second issue of this annual of science contains a frontispiece portrait of Sir William Huggins, the retiring president of the Royal Society. The aim of the Year Book is to provide a review of scientific progress during 1905, and this it accomplishes in language which is popular without being inexact, although the immense field to be covered precludes anything like a detailed résumé of recent advances. Mr. Chapman Jones contributes the section on photography, but the three pages at his disposal are quite inadequate for his purpose. Physical and chemical tables, particulars of the learned societies, and a diary for the year complete a handsomely-produced volume.

"Camera Work."—No. 13 of Mr. Alfred Stieglitz's quarterly is chiefly devoted to the work of the Austrian pictorialists Henneberg, Kühn, and Watzek, an appreciation of whom is printed from the pen of Herr F. Matthies-Masuren. Whatever one may think of the aims or accomplishments of these well-known workers, one is compelled to accord the very highest praise to the whole character of the production. It is scarcely too much to say that whatever the subject matter of "Camera Work," the influence of the editor is felt from first to last, and if we are asked to name the best example of sympathetic photographic reproduction we instinctively turn to "Camera Work," as showing what the highest culture, wedded to infinite care, is capable of in the way of magazine production. The present number will be specially acceptable to some English readers for the candid criticism of the last Photographic Salon by Mr. Fredk. H. Evans.

"ROTARY" Festivities.—By the invitation of the directorate, the employees of the Rotary Photographic Company's works, West Drayton, and their friends, spent a very jovial time in the sorting rooms of the works on Friday evening last week. It was on the occasion of the annual Christmas concert and distribution of seasonable and acceptable gifts to the workpeople from their employers.

THE Prime Minister, if we may believe the daily press, has only one hobby—photography.

## New Material.

Silk Colour-filters. Sold by A. E. Staley and Co., 19, Thavies Inn, London, E.C.

A new description of material for the dark-room lamp has been placed upon the market by Messrs. Staley in the shape of Japanese silk specially stained from formulae supplied by Dr. Miethe. The material, to judge by samples submitted to us, is in every way an excellent filtering medium for its particular purpose, being light, strong, and not subject to deformation by heat or wet. The texture of the silk imparts an agreeable diffusion to the light, and the colours of the filters, we are informed, are specially adjusted to adapt the four varieties of fabric to the different purposes of bromide printing, and development of ordinary and orthochromatic plates. The filters are at present made in yellow, red, light red, and green, and in two sizes, 7 by 5 and 11½ by 9½, at prices of 1s. 6d. and 2s. 6d. each respectively. They are certainly a noteworthy addition to the means of illuminating the dark-room with safety and comfort.

### CATALOGUES AND TRADE NOTICES

MESSRS. Rajar Limited send us the 24-page price-list of their various specialties, including the new Rajar film slide. The list gives prices for a great variety of photographic and collotype printing, and will be sent post free on request.

MESSRS. Hood and Co., Limited, St. Bride Works, Middlesbrough, are early in the field with election designs and literature, a selection of which before us is thoroughly good work, in both typography and half-tone engraving. We are glad to find the opportunities of the General Election being seized by enterprising firms.

MESSRS. EPSTEIN AND Co. notify us that they have removed their offices from Broad Street, Bristol, to Rupert Street, near to their works. The change, they believe, will be to the advantage of their customers by facilitating the rapid filling of orders. It may also be stated that Messrs. Epstein have now ready a large number of new patterns of mouldings, and have opened a separate frame department from which they are able to produce a constant variety of new lines for photographers. One frame at present in great demand is a 20 by 16 in. green and gold or walnut and gold, selling at 45s. per dozen retail.

MR. PAGE CROFT, 24, Quadrant Chambers, New Street, Birmingham, has at length placed on the market a ready-made paper for the gum process, of which we shall report further when we have tried it.

A PRICE-LIST, which is also a calendar, and a quite characteristic piece of decorative printing, reaches us from Messrs. Wellington and Ward, by whom, we have no doubt, it will be sent to any applicant.

**PHOTOGRAPHIC EVIDENCE.**—A remarkable photograph has just been added to the collection in possession of the Cincinnati (U.S.A.) police, writes the New York correspondent of the "Express," showing a crowd of 200 persons gathered near the entrance to a circus tent. The faces in the forefront of the picture can be recognised, and there are three men in it who are engaged in stealing a diamond stud and a watch from an innocent bystander. The victim is in the centre of three men. One of them is at his back, another at his right-hand side, while the third, the man who does the real work, is at his left, talking to him. The faces of two of the men were plainly recognised by the finger print department of the Cincinnati police as those of pickpockets, and one of the men was arrested later in the afternoon on the day that the picture was taken.

THE Studio Light.—In reference to the query of "Novice" in our issue of December 22 a correspondent writes:—"I find it suitable to have a supplementary light instead of white reflector as recommended, and if carefully arranged it will also light the shadow side of subject and permit of better modelling than taking the light from one source only. If 'Novice' will try the above, I am sure he will be pleased with the results. I shall be pleased to advise further if not quite clear." We will forward any letter to our correspondent.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
5	Watford Photographic Society	Members' Lantern Slides.
6	Colne Camera Club	"Switzerland." Mr. Joseph Hey.
8	Leek and District Photo. Soc.	Exhibition of Members' Prints.
8	Ulster Amat. Photo. Society	Election of Officers, &c.
8	Heaton & Dis. Camera Club	"Velox and Its New Applications" Demonstrated. Mr. W. Sadler.
8	Southampton Camera Club	Annual General Meeting.
8	Scarborough and Dis. Ph. Soc.	Amateur Photographer Prize Slides.
8	Dewsbury Photo. Society	Annual General Meeting.
8	Widnes Photographic Society	"Switzerland." Mr. O. Heslop.
8	Wallasey Amat. Photo. Soc.	Focus Slides.
8	Cripplegate Photo. Society	"The Hand Camera as a Companion." Mr. W. L. F. Westall, F.R.P.S.
8	South London Photo. Society	"Trimming and Mounting." Mr. H. Creighton Beckett.
9	Royal Photographic Soc.	"The Latent Image." Mr. J. C. Kingston.
9	Otley & Dis. Cam. & Art. Soc.	"Incarnation in Art." Rev. A. J. Saxton, B.A.
9	Sunderland Camera Club	Photography Prize Slides.
9	Sheffield Photographic Society	"The Pilgrims' Way from Winchester to Canterbury." Dr. John W. Ellis.
9	Jersey Photographic Society	Focus Stories without Words.
9	St. Helens Camera Club	"A Trip to Norway." Mr. W. H. Ward.
9	Nelson Photographic Society	Members' Lantern Slide Evening.
9	Manchester Amat. Photo. Soc.	R.P.S. 1905 Competition Slides.
9	Halifax Camera Club	Members' Evening, Slides and Prints.
9	Darlington Camera Club	Annual General Meeting.
9	Glasgow Southern Photo. Assn.	Federation Portfolio.
9	Newcastle-on-Tyne Photo. Assn.	"Some Edinburgh Notes and Views." Mr. Arthur Scott.
9	Gateshead Camera Club	"Majore" Illustrated. Mr. T. G. Davidson.
10	Edmonton and Dis. Photo. Soc.	"Principles of Composition." Mr. W. E. Tindall, R.B.A.
10	Coventry Photo. Club	Judging Summer Lantern Slides.
10	Leeds Camera Club	"Bromide Papers." Demonstrated.
10	G.E.R. Mechanics' Institution	"Carbon." Demonstrated. Mr. H. W. Bennett, F.R.P.S.
10	Huddersfield Nat. and Ph. Soc.	Amateur Photographer Prize Lantern Slide Sets, with Descriptive Lecture.
10	Everton Camera Club	(Chemical Demonstration. Messrs. C. B. Stonehouse and G. J. Drysdale.
10	Acton Photographic Society	"Wild Flowers of West Middlesex." Mr. C. B. Green.
10	South Essex Camera Club	"Belgian Trip." The President.
11	Hastings and St. Leonards P.S.	Lecture. Mr. W. A. Hubbard.
11	Liverpool Amateur Ph. Assn.	"The Platinotype Process." Demonstrated. The Platinotype Company.
11	Harrigate Camera Club	Members' Night.
11	Hull Photographic Society	Y.P.U. Portfolio of Members' Prints.
11	Rodley, Farsley, & Calverley Dis.	"Bromide Printing." Mr. J. Seaman.
11	Woolwich Photographic Soc.	"Gum Bichromate." Mr. J. C. S. Mummery.
11	Pudsey and District Photo. Soc.	Amateur Photographer 1905 Prize Slides.
11	Boit Court School of Ph. Eng.	"The Future of Illustration." Mr. Carl Hentschel (Carl Hentschel Ltd.).
11	Rugby Photographic Society	"What Can be Done with a Hand Camera." Lantern slides by C. P. Goerz.

## News and Notes.

THE business of Talbot and Eamer, 54, Seel Street, Liverpool, has been purchased by Mr. F. Strettell, who notifies us of his intention to carry on the manufacture of the cameras and other specialties of the firm on improved and up-to-date lines.

A PHOTOGRAPHIC Pilgrimage.—A number of French photographers recently made a pilgrimage to the grave of Daguerre, Bry-sur-Marne. The visit, which was paid under the auspices of the Photo-Touring Club de France, appears to have appealed to the inherent spirit of French patriotism. It is to be followed by another—to Chalon-sur-Saône, where Niepce lived and died.

A CELLULOID FATALITY.—A destructive fire broke out one night last week on the premises of the Odol Chemical Works, in Southwark Bridge Road. The premises were well alight when the fire brigade arrived, and the conflagration spread rapidly from the basement up to the first, second, and third floors. Great damage was done before the firemen obtained the mastery over the flames, and the loss is estimated at several thousand pounds. The fire originated

in the ignition and explosion of some celluloid which three men were packing. Two of them escaped, but one man was blown into a corner, and when the flames were subdued his charred body was found among the debris on the ground floor.

LECTURES on Photography.—A course of ten University extension lectures on "The Chemistry of Photography" will be given by Mr. Halford Strange, M.Sc., on Friday evenings, at 8 o'clock, commencing January 19th, 1906, in Exeter Hall, Strand, W.C. The lectures, which are to be illustrated by lantern slides and experiments, deal with the chemical action of light, the chemistry of raw materials used in photography, of negative-making and printing processes, and of orthochromatic and three-colour photography. Each lecture will last one hour, and on the same occasion a class will be held for those students who wish to study the subject more thoroughly; the object of the class being to give the students an opportunity of coming into personal contact with the lecturer, in order that they may get their special difficulties explained. The fee for the course (ladies and gentlemen) is 5s.; for Y.M.C.A. and C.P.S. members, 3s. 6d. The introductory lecture, on January 19th, is free. Tickets and a full syllabus, with lecture notes, questions, a plan of study, etc., may be obtained at the Enquiry Office, Central Y.M.C.A., Exeter Hall, Strand, W.C.

THE Free Portrait Swindle.—A woman made an application to the Tottenham magistrates last week for advice. About two months ago a man called at her residence and asked her if she wanted any photographs copied for nothing, and showed her one belonging to her next-door neighbour that he intended to do free, gratis, and for nothing. He said his firm was doing it as an advertisement. She had a photograph of her dead mother, so she gave him that to copy, and he took it away. In due course she received a postcard from the firm, which carries on business in Seven Sisters Road, asking her to call round and inspect the copy, which was finished. She did so, and found that they wanted the sum of 4s. for it. She said the man said it would be done for nothing, and they explained that they had had to discharge him for telling other people the same tale. They did not copy photographs for nothing. Applicant asked them to give her the original back, but they had refused to do so, and it was the only photograph she had of her dead mother. The magistrate instructed an officer to go round and interview the firm.

CLASSES in Photography and Process.—On Monday, January 8, at 7.30, commences the spring term of lectures and demonstrations in pure photography at the Acton and Chiswick Polytechnic. The fee till end of April is 2s. 6d. Tuesday, January 9, at 7.30, begins the term of practical workroom lessons in half-tone negative-making by wet collodion process, with incidental work in orthochromatic wet collodion. The fee for fourteen lessons is 6s. Wednesdays and Thursdays (from the 10th and 11th January), 7.30 to 9.30, are devoted to advanced negative retouching. Fee for one evening per week, 6s. per term of three months and a half. For two evenings 10s. 6d. The Polytechnic is close to Turnham Green station (S.W. and District).

A SECOND great International Photographic Exhibition will be held in Paris this year. Its venue will be the Grand Palais, and the exhibition is announced to open in the middle of July.

ETCHING with Hydrofluoric Acid. Nicholas Knight, writing in the "Chemical News" on the method of etching glass with fluor spar and sulphuric acid, points out that it is desirable to have both the surfaces of the glass coated with a thin layer of wax or paraffin; otherwise the upper surface becomes etched by the acid fumes, and the experiment is thereby marred. To obtain the desired effect, the writer for a number of years has kept an ordinary copper water-bath, 6 inches in diameter, nearly filled with paraffin. This is carefully heated to avoid burning until it is all melted. The glass object upon which the etching is to be made is immersed in this liquid and quickly withdrawn, when both sides and the ends as well are covered uniformly with a thin layer. After the etching is accomplished, the paraffin is easily removed by immersing the glass in warm water, not sufficiently hot to break it. The usual way of spreading the paraffin on one side of the glass by warming it with a small flame underneath often fractures the glass, but by the method described in the foregoing the etching is so easily and satisfactorily made that the students are eager to repeat the experi-

ment, and they etch beautiful monograms and designs on various objects—watch-crystals, drinking-glasses, paper-weights, and similar articles.

**Posocopy.**—According to the "Chemist and Druggist," Mr. Friedrich Detsinyi, Budapest, has invented a dry printing process. An aluminium plate is used as the medium, and on this any picture or printed matter is transferred. The negative impression on aluminium thus obtained is used for taking copies from in the same manner as a lithographer works. It takes about a quarter of an hour to make the aluminium plate in the first place. The process seems to be a simplified method of algraphy.

**An Artist's View.**—A writer in "T. P.'s Weekly" wonders at the tendency to overlook the fundamental difference between the artist's sphere and that of the photographer. Ruskin (he proceeds), in his "Lectures on Art," urges the definition of art as "Human labour regulated by human design," and incidentally points out the true limits of photography, which hold good to-day as they did thirty-five years ago, and, indeed, will hold for ever. Curiously enough, it is probable that no drawings from nature have ever equalled Ruskin's in their likeness to good photographs, and yet how much greater is the charm of the drawings! But these were rather laboured studies than pictures, since Ruskin never developed a personal creative power. What, then, of those pictures, faulty perhaps, or merely suggestive of facts though they may be, but through which we can gain access to a living soul? What camera has helped this Art, and how are these to be compared to the feeble and fuzzy productions all too prevalent in our modern photographic exhibitions? Surely we have here the lowest level of Art! Photographic artists!—please no; but artistic photographers we will welcome—those who recognise the limits of the camera, yet benefit by the laws of Art. And every photographer can be one of these if he but choose. Let him destroy every negative and print that does not fulfil a useful purpose of record, and in his own scientific direction let him make the most of his "human labour regulated by human design," without intruding the realm of the truly-striving artist. Art then, I think, can help the camera.

**KODAK Photographs by Royalty.**—As we go to press an exhibition of photographs entirely the work of Royal amateurs, is being opened at the Oxford Street Gallery of Kodak, Limited, at which address it will remain open to the public daily from 10.30 to 5 p.m.; Saturdays 10 to 2.

**THE Autoscope Company,** 50, Gray's Inn Road, Holborn, W.C., has amalgamated with and taken over the entire management of the Warwick Trading Company, Limited, 4 and 5, Warwick Court, Holborn, W.C., where all future communications, orders, etc., should be addressed. The whole of the present staff at Gray's Inn Road will go over to the new business, and everything will remain under their sole supervision as before.

**THE LATE G. H. JUDD.**—Many readers of the "B.J.," especially those of the "old brigade," will learn with regret of the death, after a short illness, on December 15, of Mr. George Henry Judd, who occupied important positions under the late J. H. Dallmeyer, and afterwards with the company bearing his name, for over thirty years. Mr. Judd was born in 1847, and was educated at the Enfield Grammar School and afterwards at the London Orphan Asylum, then at Clapton. After nearly twelve years' training at the Royal Small Arms Factory at Enfield he became first foreman, then manager, and for the last nine years was secretary to the firm of J. H. Dallmeyer, Limited. He did not take an active part in photographic politics, occupying himself more in promoting the interests of the London Orphan Asylum and similar institutions, being for several years vice-president and afterwards president of the L.O.A. Club. He was besides a sidesman and energetic worker at his church St. James's, Holloway. Mr. Judd leaves, besides a widow, three sons and a daughter, and his loss is keenly felt, not only by his business associates, but by a large circle of private friends, many of whom paid the last tribute of respect at Highgate Cemetery on December 21.

**MR. G. B. COWEN,** photographer, Ramsey, so we read in an Isle of Man newspaper, has presented the Ballajora Wesleyan Chapel with a beautiful copy of the tunes of the Methodist hymn-book, inscribed as an expression of goodwill.

## Commercial & Legal Intelligence.

**BANKRUPTCY of a Falmouth Photographer.**—Mr. William Marsden Harrison, photographer, of Falmouth, etc., underwent his public examination at Truro Bankruptcy Court on Saturday last. Mr. J. Dobell appeared for debtor, who told the Official Receiver (Mr. G. A. Jenkins) that he commenced business at Falmouth in 1872, and continued there until July, 1874. He was then obliged to file a petition for liquidation, but he did not remember if the estate was vested in a trustee with a committee of inspection. No accounts were furnished to him, and he did not know anything about it. He did not know if there was a dividend paid, because he never heard anything about that affair any more. He was never told about a dividend of 1s. 5d. in the £ being paid to the creditors, and never saw any accounts. Owing to the absence of the trustee no information was forthcoming regarding Mr. Harrison's affairs, and the examination was closed.

**THEFT BY A CANVASSER.**—At the Burton Police Court, on Friday, Charles Fenton, a youth of 16, and described as a canvasser, of Lichfield Street, Tamworth, was charged with stealing a photograph, valued at 1s. 6d., the property of George Gilbert, on December 18. Mrs. Ellen Gilbert, wife of the prosecutor, stated that the prisoner came to her house three weeks ago canvassing. He also came at 6.30 on December 18. She had given him the first time an order for an enlargement, and the second time he brought the enlargement and the photograph back. She paid prisoner for the work, and when he had left she missed the cabinet photograph, which she had placed on the table. Her son saw Fenton pick up the photograph and followed him to the railway station. Police-Constable Smith deposited to receiving the prisoner in custody from the Tamworth police, and in reply to the charge he said he was followed to the railway station. Prisoner said he did not do it with intention. The mother asked for leniency, and prisoner was bound over under the First Offenders' Act, with costs (3s.).

**C. J. CULLIFORD AND SONS, LIMITED.**—Registered December 12. Capital, £25,000 in £1 shares. Object, to carry on the business of stationers, printers, lithographers, photographers, art printers, etc., and to take over the business carried on by H. T. Culliford as C. J. Culliford and Sons. No initial public issue. The first directors are H. T. Culliford and J. J. Edwards (both permanent). Remuneration, £100 each per annum, plus £500 per annum for H. T. Culliford as managing director. Registered office: 14 and 15, Fulwood Reuts, Holborn, W.C.

**DAVY HILL AND HODGKINSON, LTD.**—Registered December 22. Capital, £100,000, in 95,000 Preference, 2,000 Preferred Ordinary, and 3,000 Ordinary shares of £1 each. To carry on the business of manufacturing chemists, importers, exporters, manufacturers of chemicals for pharmaceutical, technical, photographic, scientific, and other purposes, etc. No initial public issue. The number of directors is not to be less than two nor more than five. The first are: C. Hodgkinson, F. Clarke, A. Hicks, and C. A. Hill. Each of the three last-named may retain office for life. Qualification, £1,000 shares or stock. Remuneration, as fixed by the company.

## Correspondence.

- \* \* Correspondents should never write on both sides of the paper. All notice is taken of communications unless the names and addresses of the writers are given.
- \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### A WAGES QUESTION.

To the Editors.

Gentlemen,—This subject cropped up in your answers to correspondents, December 21, 1900. Various letters appeared, one from the undersigned on January 4, 1901, also from John A. Randall, and "An Employer" on January 19, 1901, and later on one from "G. W.," chiefly in reply to Mr. Randall.

The editor's advice was: "Do not relinquish present employment." My employers seem content to retain my services, and I have, so far, remained with them, I venture to hope, to our mutual satisfaction. Since the above date I have had two additions to my salary,

so that I am now earning 19s. a week extra on the £6 6s. I was then receiving, and I am in hope of obtaining 10s. a week extra before 1906 has passed, as I anticipate being made foreman of the photograph department. At present we do without one.

The firm depreciate our time, and if this occurs they only pay at the rate of 1s. 6d. per hour, and I now have to put in three to four hours most Saturdays. In addition I now make half-tones and print zinc plates for litho work. This is extra on the work I did in 1900.

My real object in writing is to interest those intelligent operators who can command 50s. to 60s. per week to take up the study of work outside their own horizon, like collotype, photogravure, tri-colour, photo-transfer, line, half-tone, enlarging, lantern slide making: even blue printing, ferro-prussiate or ferro-gallic are all helps. St. Bride Institute, Bolt Court, Cripplegate, and the various Polytechnics, are all advantages which are sadly neglected by operators and printers in London.

I spent nearly five years qualifying for the position I now hold, and in the summer of each year I arranged to work the process I had learnt in the winter with some small man, generally giving him my time and in one case my money also.

Let me add, engineering firms in the north are glad to give £4 for a good man, and I am informed of one man who is paid at the rate of £6 a week who can reduce an original down to within 100th of an inch and make cyanide or ferro prints afterwards. All this class of work also demands careful stopping out, also machinery is photographed, and much retouching done on the negative.

I am working with two men who are now getting £6 and one who has £7, besides several who obtain £5, all in commercial work.

I have only two rules by which success may be obtained (1) Turn out the very best work possible, and (2) keep your promises as to time, and, if possible, be five minutes in advance.

Finally, don't walk in as the clock is striking but endeavour to be at work when it does. This should mean an hour to an hour and a half every week in favour of your employer. Only once in ten years have I arrived as late as five minutes to the time of starting work.—I am, Gentlemen, yours truly,

COMYN,

A BOLT COURT STUDENT.

December 27, 1905.

## FREE PORTRAIT SWINDLES.

To the Editors.

Gentlemen,—I am sure my brother professionals must be grateful to you for the frequent exposures in your pages of the free portrait pest to our profession. The presence of these gentry in a district is an evil which can be fought in no better way than by acquainting the public with the plain statements of their methods in various places such as you have—unfortunately—been able to record of late. I have found that customers of my own have been taken in by the plausible tales of firms of this kind; but when I have shown them the reports of similar businesses as reported in the B.J., they have recognised the underhand nature of the offers which have been made to them. I am prepared to fight the next attacks on my custom by these "free-traders" by circularising my clients with a few excerpts from the JOURNAL, reprinted with headlines and references to the source of publication, and would personally express my satisfaction that the JOURNAL places this power in the hands of all of us.—Yours faithfully,

C. HIMMINS, Manager.

Glasgow, January 1, 1906.

## COLLODION EMULSION.

To the Editors.

Gentlemen,—In reference to the recent article reproduced in your issue of December 29, may I take the liberty in signalling a slight error.

It is stated that the emulsion is more convenient in the dry state, but this only because it is easier to pack for travelling and carriage becomes insignificant, whereas the emulsion can only be forwarded per goods train. But as regards use we think the one as good as the other, and have no preference for the dry.—Yours very sincerely,

H. CALMELS.

150, Boulevard du Montparnasse, Paris.  
December 30, 1905.

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

## PHOTOGRAPHS REGISTERED:—

A. D. Coon, 72, Park Street, Dundalk, County Louth, Ireland. *Photograph of the Members of the Dundalk Theatrical Club on the Stage of the Dundalk Town Hall, taken by Flashlight, December 12, 1905, in Costumes of Play entitled, "The Checkmate."*

F. C. Clarkson, Royal Studio, Colchester. *Seven Photographs—Lady Pearson; Sir Westman D. Pearson, Bart.; Mrs. Worthington Evans; Laming Worthington Evans, Esq.; H. K. Newton, Esq.; Mrs. Levy Lever; A. Levy Lever, Esq.*

T. F. Pearson, 352, Christchurch Road, Boscombe, Bournemouth. *Photograph of unique Post Office at Lford, near Christchurch, Hampshire.*

J. Pottle, Eastbrook, Wimbome. *Photograph of Lord Alington's Shooting Party Group at Crickel, December 6, 1905. Photograph of His Majesty presenting Cup and Medals to Swanage Volunteers at Wimbome Railway Station, December 5, 1905.*

L. Berry, 27, Chapel Street, Chorley. *Two Photographs of Lady Balcarres.*

A. H. De'Ath, 32, Bank Street, Ashford, Kent. *Photograph of P. Harris, Esq., Liberal Candidate for the Ashford Division of Kent.*

P. M. Lee, 2, Endsleigh Place, St. Marychurch, Torquay. *Three Photographs of F. L. Barratt, Esq., M.P.*

PHOTOGRAPHS ON CELLULOID.—Can you tell me how to do miniatures on celluloid? I believe they are done on P.O.P. and then coloured, and in some way put on the celluloid. I find I cannot get the print to stick to the celluloid. Is it necessary to use an adhesive roller, or is there any way I can squeeze the print on so that when it is dry it will not peel off?—D. G.

The prints are moistened with alcohol and hot rolled into contact with the celluloid. Write to Mr. Jonathan Fallowfield, 146, Charing Cross Road, for his photo-button catalogue (6d.), which will give you the information.

DUNDALK.—The postcard is printed from a half-tone block. You will find the advertisements of several firms doing work of this kind in our pages.

INTENSIFIER.—If a drop of intensification mercury dries on a varnished negative would it chemically affect the P.O.P. that might afterwards be printed from it. 2. Is "iodide" poisonous?—CHEMISTRY.

1. Certainly P.O.P. coming in contact with mercury chloride will be prevented from printing. 2. Yes, but not violently so.

SILVER RESIDUES.—1. Could you tell me roughly how much liver of sulphur it will take to throw down the silver contained in 500 gallons of old fixing bath? 2. What test can I apply to ascertain when all the silver is deposited? 3. Is there any silver in bromide developing solutions worth throwing down as residues? If so, how is it precipitated to that state ready for the refiner?—I.

1. Impossible to say. If the baths were completely saturated with silver bromide, the quantity of sulphide would work out theoretically to 50 lbs. But it is not likely that it will approach this figure in practice. 2. Add a little liver of sulphur solution to some of the clear liquid. A further dark precipitate indicates that the silver is not all down. 3. Not worth recovery.

A. D. COON.—We should think your requirements would be met by the Short portarit lamp, a description of which you will see on page 1156 of the "Almanac." Any electrical fitter would make you the battery and ignition device.

DEVELOPER.—I have recently made a trial of a developer which I saw quoted in the contributed notes in the "Annual." It is

described as a "process" developer, and the formula is somewhat as follows:—Metol 40 grs., quinol 50, sulphite 120, water 20 ozs.; No. 2 consisting of 180 grs. caustic potash in 20 ozs. I like the way this brings the image out in the case of preparing enlarged negatives from carbon transparencies, but I find that the developer discolours immediately after mixing, and the negatives are much yellow-stained. I want to get a clean negative, using this developer. Will an acid-fixing bath meet the case? I have not been using one. Or will an extra amount of sulphite prevent staining, and not interfere with the action as at present of the developer? What I mean is, that I want the image to come up at once, and to acquire full density quickly. Shall be much obliged for your kind information.—J. H.

Either plan will diminish the stain. If you do not find the first sufficient, try the second.

**BOOK ON LIGHT.**—I shall feel obliged if you will recommend a book treating in a plain manner upon the phenomena of light and colour, not necessarily in relation to photography. If some simple experiments are described therein it would be the very thing I want.—STUDENT.

"Light, Visible and Invisible," by Professor Sylvanus P. Thompson.

**OWNERSHIP OF A NEGATIVE.**—A customer of mine sat for portraits. Soon after this she wrote and asked for the negative, a request which I politely declined to accede to. I received another letter saying that the negative by law was her property, and that in some cases of the kind recently decided the negative was ordered to be given up. I maintain that the copyright only is vested in her, and that I cannot sell or supply any copies to anyone but herself, but that the negative is my property, booked up in my register and forms not only part of my stock, but one of the assets of my business. If she is right in making this claim the numbering and listing of one's negatives may be at any time rendered useless work. The negatives might as well be packed up and sent with the prints to each customer.—R. H. RAMSDEN.

The negative is absolutely yours. All the decisions of the courts uphold this right of the photographer. You will see a reference to one or two in the article on "Photographic Copyright" in the current "Almanac," p. 675.

**COPYING FADED PHOTOGRAPHS.**—We have an unmounted print on salted paper, taken in 1850, which is rather valuable, but very much faded. Some years ago we used to revive this kind of print, but have quite lost sight of the formula. Could you assist us in the matter? It would not matter if the print came up uneven, as we have to copy it, but it is very faint in its present state.—G. WEST AND SON.

The formula to which you refer is probably a somewhat dilute solution of bichloride of mercury. That will remove the yellowness and brighten up generally a gold-toned print, and render it better for copying. It will not, however, restore any lost detail. As the print you have to deal with was made so long ago it is doubtful if it was toned with gold, in which case the treatment might be injurious. We should advise you to copy the print as it is, using an orthochromatic plate. It is often surprising how well old faded photographs copy without any treatment whatever.

**H. MALLETT.**—If a person sells his business, and it is stipulated that he shall not set up in business or be concerned in any within a certain radius, he is bound by the agreement. If he practises photography for gain within that radius, although he may reside outside it, we should say it would be illegal. Otherwise agreements might easily be evaded. With regard to the undue restriction of trade, that is a very vague term. What, in law, might be so termed under some circumstances might not in others. For example, if an agreement were made that a person should not practice photography within, say fifteen miles of St. Paul's it would probably be classed as an undue restriction of trade. But if it were for the same radius of a country town the case might be just the reverse.

**J. WIDEROR AND Co., AND J. W. C.**—The address of the makers is Heselike and Co., No. 2, Lützow-strasse, Berlin, W. 35.

**LENS QUERIES.**—1. I have a 22in. telescope, and should be glad to know whether it would be possible to use the negative combina-

tion of same in front of an ordinary lens for tele-photo work, or would it need to be corrected to chemical focus? 2. Also, are the cheap supplementary lenses on the market so corrected or not?—TELESCOPE.

1. By negative combination we presume you mean the negative lens forming part of the achromatic object glass. This is most probably cemented to the positive lens, in which case it cannot be separated from it without spoiling the telescope. It might serve fairly well as a supplementary lens, but an ordinary spectacle lens, costing only a few pence, will probably do as well, if not better. Being of heavy flint glass, the telescope lens might show the effects of want of correction. 2. The cheap supplementary lenses are uncorrected, but being specially selected for their purpose they act fairly well, and one of them will probably give you more satisfactory results than any makeshift of your own. You can get corrected lenses, but if you do not wish to go to that expense we would advise you to buy one of the cheaper ones. Select the largest diameter lens that will fit your lens hood. If you do not, the mount of the supplementary lens will cut off much of the view.

**WINDOW BLINDS.**—Could you kindly oblige by giving me the name and address of a firm, or several, who can supply shop-window blinds, and can insert lettering on same?—INTERESTED.

Such shop-fitters as Potter and Co., Aldersgate Street, E.C., or Sage and Co., Gray's Inn Road, E.C.

**COPYING.**—Kindly tell me how to get best results when copying blue prints and type-writing in violet ink.—H. G.

Use a deep yellow or a red screen on a green-sensitive plate. You will find an article on the subject, with formulæ, on page 775 of the "Almanac."

**W. HARRISON.**—Probably Valentine, of Dundee.

**A. E. (Barnsley).**—The registration applies to reproduction in any size. In regard to the separate copyrights you should obtain a written assignment at the time of the sitting if you wish to be on the safe side. See par. 28 of the article on "Photographic Copyright" in the ALMANAC.

**PHOTOGRAPH ADVERTISEMENTS.**—A curious case, involving the question of what is the legitimate use of a photograph is arousing much interest and amusement at Pittsburgh. Miss Evelyn Nesbit, the once well-known American actress, now the wife of Mr. H. Thaw, a millionaire of the region, recently found that her former fame has been utilised by a butcher of the city to advertise ham and pork sausages by means of a poster representing the lady reclining her head on that of a Polar bear. The title of this idyll was "Beauty and the Beast." Though not intended to cast any reflection upon Mrs. Thaw's husband, this poster has aroused the ire of her mother-in-law, who has taken the most drastic means known to law to have the posters suppressed. The "Globe's" comment upon the incident is that the butcher pleaded, but Mrs. Thaw was as ice.

**MESSRS. Lambert, Weston and Son,** of Folkestone, last week obtained a flashlight photograph of the audience in the Pleasure Gardens Theatre. The picture has been exhibited at their studio, and has elicited some favourable comment in the local press.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY

An exhibition of colour photography will be opened in London next week. (P. 22.)

Some necessary preliminaries to successful carbon printing are discussed on p. 22.

At the Lord Mayor's fancy dress ball over 400 negatives were taken by arc light between 6 and 11.30. A special report of the method adopted appears on p. 25.

The R.P.S. Progress Medal has been awarded to Professor Janssen, of Paris, for his work in astronomical photography and his researches in reversal. (P. 24.)

Some further advice on the way a photographer may impress his customers by good taste in stationery appears on p. 25.

The bleach-out process of making colour prints at one exposure from a coloured transparent original appears to be approaching a commercial stage. Directions for the use of a sensitive tissue have been issued. (P. 26.)

Instructions have been published for the toning of silver prints with sulphide, with and without the assistance of a combined bath. (P. 28.)

Some peculiar phenomena in the drying of gelatine and collodion film containing salts have been observed by R. E. Liesegang. (P. 29.)

An exhibition of portraits of prominent personages in London society by H. Walter Barnett has been held in the studio of J. C. Strauss, St. Louis. (P. 31.)

A new kind of tube for dry cartridge chemicals has been patented. (P. 32.)

The photographer's advertisement should be an argument to the reader—the reason why of the photographer's merits, not merely a statement of them. (P. 32.)

Stereoscopic effect in cinematograph pictures is again the subject of a patent. (P. 33.)

## EX CATHEDRA

### The Sun's Biographer.

**The Sun's Biographer.** There is a peculiar fitness this year in the award of the Progress Medal of the Royal Photographic Society to Dr. Janssen, for no man has done more to tell us what the sun is like, and the camera has been the means by which he has shown us the structure and fiery moods of the source of all photography. In his own country photographers have not been so long in recognising his scientific applications of the camera. The French Photographic Society awarded him a medal thirty years ago, but the magnitude of his work in astronomical photography has its graphic record in a presentation by M. Janssen himself to the French Academy of Sciences a year or two ago. The gift was an atlas of the sun drawn by photography, and to produce it six thousand negatives had been taken during a long series of years. The atlas records all the tremendous physical changes of which the sun and its surrounding envelopes are capable. It is, in fact, a kind of photographic biography of the sun during the years between 1876 and 1903.

\* \* \*

## A New Discovery?

**New Discovery ?** "Revolutionise photography" is a favourite phrase of the inventor ignorant of the field in which his revolution is to come to pass. We have heard the phrase applied many a time, but we have had to wait for the old order to change. But about the naivest claims to revolutionary potency which we have seen for a long time appears in a periodical issued under the ægis of what professes to be some sort of college of photography—in America. We read that a glass plate has been perfected which will replace the ground glass of the camera, and will remove all colour, giving simply the high-lights and shadows. This stupendous achievement is the work of the Monochrome Glass Company, and is heralded with the headline, "Will revolutionise artistic work among both amateurs and professionals." Has the writer ever heard of such a thing as a blue focussing screen?

\* \* \*

### Three-colour Without Filters.

**Three-colour Without Filters.** During the early part of last year a patent was sealed in Great Britain, and, we believe, in other countries, for the production of the three-colour sensation negatives without the intervention of light-filters of any kind. Indeed, the patentee's claim is wider than this, and applies to methods of colour photography without respect to the number of negatives on which the colour records shall be made. The essence of the patent consists in the decomposition of the image formed by an ordinary lens into a spectrum. The various parts of this spectral image are then deflected by

suitable arrangements of prisms and transmitted by a series of objectives on to the sensitive plates. Herr C. J. Drac, the patentee of the apparatus constructed on these lines, has recently given us the opportunity of witnessing the visual performance of the first working model. The apparatus consists, first of an ordinary photographic lens, behind which is mounted a direct vision spectroscope by which the rays from the lens are decomposed into a spectrum. In the plane in which this spectrum is formed are two prisms, separated by a space which can be adjusted at will so that any required central part of the spectrum can pass directly to the second series of lenses—numbering three in the camera we inspected—whilst the prisms on either side displace the outer portions of the spectrum, producing altogether three parallel beams of light which form their respective image in the focal plane of the triple set of lenses. The adjustments of the two prisms provide for the splitting of the spectrum at practically any two points, and the optical system of the instrument also includes other prisms to correct the aberrations of the decomposed beams, and to produce three images of the same size and of optical perfection. The camera as it stands is reversible: on inserting a positive transparency in place of the ground glass an image in natural colours is projected by the original taking lens, or can be viewed on looking into the objective. The analysis and synthesis of the light in the respective operations of taking and projecting are thus performed without the aid of filters, though we prefer to reserve any comments on the results until we have also witnessed a photographic demonstration of the method.

#### **An Exhibition of Colour Photography.**

In view of the great and increasing interest taken in colour photography, it is a somewhat remarkable fact that no exhibition solely devoted to this subject has been yet held in this country. A collection of photographic and photo-mechanical prints in colour was brought together last spring in Paris, by the Comité d'Etudes Photochromiques, but unless we except the exhibits of colour photography which have turned up at the leading photographic exhibitions, principally at that of the Royal Photographic Society, the public has had no opportunity to examine side by side the results of processes which are at disposal at the present time. We may, therefore, assume that some interest will attach to the announcement that such an exhibition has been organised by **THE BRITISH JOURNAL OF PHOTOGRAPHY**, and will open immediately. In our next issue we shall be able to declare it open and extend to every one of our readers a cordial invitation to pay it a visit.

\* \* \*

#### **Photography at the Society of Arts.**

Two forthcoming fixtures at the Society of Arts should be noted by photographers able to attend the meetings at the society's impressive—we will not say gloomy—premises in John Street, Adelphi. They are "The Artistic in Painting and Photography," by J. C. Dollman, and "The Production and Collection of the Picture Postcard," by Frederic T. Corkett. As manager of Raphael Tuck's postcard department and one of the pioneers in the picture postcard cult, Mr. Corkett should be able to speak authoritatively on his subject. But we are surprised to see that the collection of postcards enters into his discourse. Imagine any of the audience at the Society of Arts being advised on the best methods of accumulating examples of this modern scourge of middle-class society.

## **PRINTING PROCESSES.**

### **XVII.—CARBON.**

CARBON printing, alike in theory and practice, is essentially different from any of the processes previously dealt with in this series of articles. Not only is it different, but it offers advantages that are not possessed by any other photographic printing method. Carbon pictures may be on any kind of support—such as paper of any tint or surface, opal glass, porcelain plaques, wood panel, metal, jewellery or the like. And the picture can be of any colour or tint that may be desired, and that without the trouble of toning, and with the assurance that all the prints will be of exactly the same tint. This cannot be assured with any other process. With bromide printing and after-toning, as described in previous articles, a great variety of colours may be obtained; but it is tolerably well known that, with the exception perhaps of the "sulphide" sepia, there is a great difficulty in getting even half a dozen copies of exactly the same tint. In some of the methods of toning bromides the stability of the results is of a very doubtful nature—to say nothing of the trouble involved when two or, perhaps, three distinct operations have to be very carefully performed. With the carbon process there is no more trouble in producing one desired colour than another. The operations are the same in every way, whether black, blue, green, or any other colour or tint is required, and, what is more, with this process the results are undoubtedly permanent.

It may be asked why, if all these different advantages are possessed by this process, do people first produce bromide prints, and when finished go to all the additional trouble of toning them to get, after all, only uncertain results, when they can secure all they desire by the most simple means? The explanation, we think, is that those who have not given the carbon process a trial are under the impression that it is a difficult one to work, and that special appliances are a necessity. This is a fallacy of old standing, and one which requires only a trial of the process for its dissipation. One thing, possibly, that has deterred some whose experience has mainly been confined to P.O.P. from trying this printing method is that there is no visible image as a guide to the right exposure. But there is a greater latitude in exposure allowable with carbon than with any other printing method, so that a print need rarely, if ever, be lost through error in the exposure. It is not our intention to enter into a lengthy disquisition on the theory of carbon printing or even to explain every detail and element of the process—the text-books do that well enough—but we desire to pick out a number of points to which special attention is necessary, and which are the causes of half the alleged inexplicable difficulties of the process. It is hoped that even some present carbon workers may learn something from notes drawn up in this way.

If the tissue be purchased ready sensitised—and it is now supplied commercially in a great variety of colours in that condition—no chemicals whatever are required from beginning to end, beyond a solution of alum, and even that is not absolutely necessary. It is a great convenience to small workers to buy the tissue in the sensitive state, as then the little trouble of sensitising is avoided and the user ensures having it in the best condition for working. In the sensitised state the tissue can be kept, at this time of the year, for two or three weeks, if kept dry and fairly well protected from the air. A simple, and effective, way of preserving it is to put it into a printing frame of the box form with a few sheets of blotting paper, which have been thoroughly dried before the fire, at the back, and then close up the back tightly. Preservative

cases, provided with chloride of calcium, are on the market, and in these the sensitised tissue will remain in good working condition for several months. A tin case, such as employed for the storage of platinotype paper, may be used with equal result. If one of them be used it will be well to roll the tissue up, prepared side outward, as then there is less likelihood of the coating cracking when it is unrolled should it happen to become abnormally dry from the extraction of its moisture by the chloride of calcium.

In a first essay in the carbon process we should, for the reasons mentioned above, advise that the tissue be purchased ready sensitised, and this we shall assume is done. A query we have frequently had to reply to in the Answers column is:—Why does the printed tissue sometimes refuse to adhere to the support when squeezed upon it for development, or perhaps, when it does adhere, why does the backing refuse to strip in the hot water? The answer is simple; the tissue, from some cause or other—long keeping or possibly exposure to light—has become insoluble. Trouble and disappointment from this cause may easily be avoided by testing the tissue before printing it, which is very simply done. Cut off a small strip and put into cold water for three or four minutes, then transfer to warm water—say at a temperature of about 100 deg. Fahr. If the coating at once begins to dissolve we shall know that the tissue is in good condition. If it does not the heat of the water may be raised by another ten degrees; then if it dissolves it will still be workable, but it will have gained in sensitiveness by the keeping, and a somewhat shorter exposure in the printing should be given, and rather warmer water than usual employed in the development. Sometimes by long keeping, or exposure to light, it will be found that as the coating dissolves at the higher tem-

perature, a thin film may be seen floating in the water. This shows that the tissue has become "tinted"—that is, slightly fogged. Such tissue is still workable, and, for some negatives, *i.e.*, those of hard contrasts, is a decided advantage. It is specially suited to hard ones. With negatives of this character it is very common with experienced carbon printers—after the exposed print is taken out of the frame—to expose it for a few seconds to the light to produce this partially insoluble film in order to get from such negatives a harmonious result. If at the higher temperature the pigmented coating refuses to dissolve the tissue is useless, and it would be a waste of time to attempt to employ it.

In printing by the carbon process it is essential that the margins of the tissue are protected from the action of the light, otherwise it will be liable to come up or frill at the edges during the development. Therefore, it is necessary to provide the negative with what is known as the safe edge. This may be a line of black varnish, a quarter of an inch or so wide, run round the negative with a brush: or a cut-out mask of black or yellow paper which will serve over and over again may be used. The safe edge is, preferably, put on the glass side of the negative so that it is slightly vignettied in the printing, as a sharp outline coming against a very deep shadow in the picture is not so safe as a less abrupt one. If, however, the picture is required to be printed with a white margin as many carbon pictures are, particularly those on drawing papers, the safe edge must be on the film side. The best safe edge in this case is a strip of thin yellow or black paper, or tin-foil, neatly gummed on the margins of the negative of sufficient width to protect the tissue to its extreme edges.

The next article will deal with the printing and development of the pictures.

## PHOTOGRAPHY AT THE MANSION HOUSE.

The programme of the Juvenile Fancy Dress Ball, held on January at the Mansion House, bore the following announcement on the back page:—

### NOTICE.

Miss Annie Bell, of the Photographic Studio, 179, Regent Street, W., will be in attendance during the evening in the Entrance Hall (downstairs), to receive sittings from any of the children guests whose parents may wish them to be photographed.

Photographing commenced at 6 o'clock, the Lady Mayoress, Mrs. Torbay-Steer, exposing a plate, which proved a very successful picture, on the Lord Mayor, the Rt. Hon. Walter Vaughan Morgan, and his grand nephew, the Lady Mayoress's little son, who was dressed as King Edward VI. From then until 11.30 there was a constant stream of juvenile sitters, over 400 photographs being taken in all. Several dozen of the exposed plates were developed during the night, and prints were in the hands of the Press agencies by 11.0 the next morning.

Miss Bell herself was at the camera with an assistant for focussing and manipulating the dark slides, while another assistant moved the new accessories in use and helped the little sitters on and off the platform. All the organisation for numbering and changing the plates, and the arrangement and fitting up of the electric light Miss Bell placed in the hands of the Polytechnic School of Photography, Regent Street, W., of which she was a student before opening her business. The fact that during one hour over a hundred exposures were made, and that the whole evening's work was carried through without a hitch, speaks well for the thoroughness of organisation and the care with which every eventuality was anticipated and provided for.

As the negatives are of extremely good quality it will no doubt interest professional workers if we give a description of the arrangement of the artificial light, which was practically that in constant use in the studio operating classes at the Polytechnic School. One of the Westminster Engineering Company's large enclosed arc lamps was suspended in a 6ft. umbrella-shaped reflector at a suitable height, and yet as near the sitter as possible so as to give the maximum illumination. A three-fold screen covered with white blotting paper was so arranged as to increase the illumination towards the sitter, and at the same time cut off direct light from the camera and lens, thus avoiding any danger of flare and the use of a focussing cloth. The shadow side was lighted by a blotting paper reflector of large size. A diffusing screen a yard in circumference, covered with tracing linen, was placed to cut off direct rays from the head and upper part of the sitter, and to allow uninterrupted illumination of the feet and floor, and of the shadow side reflector. The large amount of reflected light from the three-fold screen prevented the least trace of any shadow of this diffuser being present. The plates used were 250 H. and D., and with a Ross Homocentric lens at F/5.6 the exposure was 1-3 second, or practically a studio snap.

We do not know that the enclosed type of arc lamp has ever before been employed for a similar piece of work, and the fact that running on a 200 volt current for five and a half hours it was only necessary to raise the lower carbon twice, and to replace the top carbon once should convince portrait photographers of the entire suitability of these lamps, and in a thoroughly practical manner vindicates the constant advocacy which they have received for portraiture at the Polytechnic School of Photography during the last few years.

# THE PROGRESS MEDAL OF THE ROYAL PHOTOGRAPHIC SOCIETY.

AWARDED TO PROFESSOR JANSSEN.

ON Tuesday evening last, January 9, at the meeting of the Royal Photographic Society the announcement was made that the Council had awarded the Progress Medal for the year 1906 to Professor Janssen for his "work in astronomical photography, his researches in reversal, and other photographic investigation."

The medal, which was instituted in the year 1878, is granted "for important advance in the scientific or artistic development of photography," and has previously been awarded to the following for the reasons stated:—

1878.—Captain W. de W. Abney. For his scientific work in the advance of photography.

1881.—W. Willis. For the platinotype process.

1882.—L. Warnerke. For general progress and his discoveries in photography: actinometry, sensitometry, instantaneous shutter, gelatine emulsions, etc.

1883.—W. B. Woodbury. For the Stanotype process.

1884.—Dr. J. M. Eder. For his work respecting gelatine chloride emulsions.

1890.—Captain W. de W. Abney. For his continued work, experiments, and investigations in photography.

1891.—Colonel J. Waterhouse. For his original and continuous researches in relation to orthochromatic photography; the successful elaboration of a process of photographic etching; and the direct production of reversed images by the use of thio-carbamides in the developer.

1895.—Dr. P. H. Emerson. For his work in the advance of artistic photography.

1896.—Thomas E. Dallmeyer. For the telephotographic lens.

1897.—Professor Gabriel Lippmann. For his discovery of the process of producing photographs in natural colours by the interference method.

1898.—Hurter and Driffield. For their work in the determination of the speed of plates.

[Photograph by]

DR. C. J. JANSSEN.

[Boissonnas, Geneva.]

Awarded the R.P.S. Progress Medal, 1906.

1900.—Louis Ducos du Hauron. For having initiated three-colour heliochromy as a working process.

1901.—Dr. R. L. Maddox. As the inventor of the gelatino bromide of silver emulsion dry plate process.

1902.—Joseph Willson Swan. For his services to photography in connection with the carbon or pigment process and its applications.

1903.—Frederic Eugene Ives. For his work in three-colour photography.

1904.—Dr. Paul Rudolph. For his researches in photographic optics.

M. Janssen, who has now passed his eightieth birthday, has had many scientific honours in his time, and has occupied many positions in astronomical and photographic life. In 1877 the French Photographic Society conferred its "grand medaille" upon him for his photographic work in astronomy. Ten years later he was

President of the Academy of Sciences, and in 1893 he received the Peligot medal of the French Photographic Society, whose president he was for one session. When the Congrès International de la Photographie was founded in 1889, he was its first president, and to-day he fills the same office in the Union Nationale des Sociétés Photographiques de France. He is a member of the Council of the Legion of Honour, and at the present time, despite his great age, discharges the many duties which his position as a leader of science in France lays upon him. We publish below a short account of M. Janssen's labours by M. Leon Vidal. The photograph, by Boissonnas, was taken some five years ago.

## AN APPRECIATION OF DR. JANSSEN.

By Leon Vidal.

THE life of M. Janssen has been devoted to astronomy, yet it is not of his purely astronomical work that one must speak, only of that part of it which is related to photography. Probably every one has a general notion of the great and valuable services which he has rendered in the application of photography to, particularly, solar astronomy, yet few are familiar with the long series of investigations dating from about the year 1874. It was about this time that M. Janssen exhibited to the Academy of Sciences a photograph of the transit of Venus, obtained with the "photographic revolver," an instrument of his own invention, by means of which 48 images, or twice or thrice this number, could be taken. The instrument was a remarkable one for that day. It permitted of the adjustment of the total time of exposure, and of the interval between each exposure; it was automatic and, if necessary, could be held in the hand while in operation. In the same year (1876) M. Janssen made photographs of the sun 18 inches in diameter from his observatory in Montmartre. In a communication about this time to the Academy of Sciences he forecasted the great part which photography was to play in physical astronomy:—"Celestial photography is now entering a new channel: up to now it has only been used to obtain faithful records of phenomena. It is now proceeding to the more important duties of discovering facts which escape investigation by our optical instruments." Only two years elapsed before he confirmed the truth of this prediction by photographing the "rice grain" structure on the sun. The photograph was an enlargement to three diameters from a negative 18 inches across and made with an exposure of 1-3,000 of a second. It showed the granulations of the sun surface and the regions where these granulations are effaced by vast rising streams of hydrogen gas.

Many other of M. Janssen's astronomical photographs must be passed over until we come to the year 1880, in which he made a communication to the French Academy of Sciences which aroused as much interest in its purely photographic respects as in its astronomical relations. It was on the reversal of photographic images by over-exposure. It was shown that in the case of the negative photographic images produced on a sensitive plate, increase of the exposure converted these images into positives. "At Meudon," wrote Janssen, "our images of the sun are obtained with an exposure which varies with the state of the atmosphere and the nature of the subject, but this period of exposure is rarely more than 1-1,000th second when it is required to obtain

detail in the photosphere. In the case of gelatine plates, the exposure may be very much less—1-20,000th of a second and less. Under these conditions if a plate receives an impression of a half or a quarter of a second—i.e., ten or twenty million times as much, the action of the developer shows a positive—i.e., the disc of the sun white and the spots black, as is seen in the telescope. This positive image is obtained with all the delicacy of the negative one. Between the two extremes of exposure there is a point at which the image is neither negative nor positive—the plate is uniformly veiled—and if, on the other hand, a longer exposure still is given than is necessary for the production of positive image, this latter in turn disappears and the developer discloses only uniform transparenence on the dark ground of the sky. This ground itself disappears on prolongation of the action of light." This second state of reversal which Janssen discovered in his solar photography was afterwards confirmed by Brebner and Krone.

Janssen himself was occupied not so much with photographic theory as with the application of this curious phenomenon, and proposed to employ reversal in obtaining photographs of the sun's penumbra showing both the granulation and details of the chromosphere.

M. Janssen was continually applying his photography to astronomical purposes. In 1881 he read a paper on photographic photometry, taking the result of the action of light as the measure of the radiation from a celestial body. In 1893 he was at work on the spectro-photography of the chromosphere. He placed before the sensitive plate a second slit to isolate in the spectrum the particular rays forming the image. He had suggested this method so long before as 1869.

When quite an old man M. Janssen founded the observatory on the summit of Mont Blanc, and himself made the ascent of the mountain a number of times to pursue his observations in the clear and rarefied air of the highest point in Europe.

The very great extent of M. Janssen's work requires more lengthy consideration than can be given it with the space of such a review as the present one, but as a last word it may again be said that he deserves to be considered as one of the most strenuous and whole-hearted exponents of photography applied, not only in a general way, but especially in scientific astronomical photography. He is one of the great men of photography.

LEON VIDAL.

## PHOTOGRAPHERS' STATIONERY.

## II.

LAST week's article having dealt with the photographer's correspondence with his sitters, a few notes on that with the firms from whom he obtains his supplies, may not be out of place. Whether or not it be thought necessary to adopt any systematic method of transacting business with the sitter, there can be absolutely no question as to the necessity for so doing with the wholesaler. The tendency nowadays is for wholesale houses to widen the scope of their activities, and, consequently, their work can be, and is, subdivided into more numerous departments, and the photographer who is systematic in his correspondence will find that he receives much better service from them. There is no better means of doing this than by using duplicating or manifold books, preferably with the pages numbered, by which a copy of all correspondence is retained. For instance, in the event of any mistake in the execution of an order, the photographer is able to satisfy himself that his order was sent in as he intended it should be, and then, by mentioning the order number in his letter of complaint, he renders it easy for the dealer to refer to his order as received by them. Judging by the imprint on the invoices of most of the leading dealers

one firm of printers makes a specialty of this class of work, and doubtless they would be willing to supply professional photographers. Although these manifold books are desirable for correspondence with the wholesaler they must not be used for writing to the sitter as they cannot be said to maintain the necessary appearance of dignity.

## The Price List.

Years ago when albumen was the only process and gilt-edged Bristols in a few unvarying sizes the only mounts, the photographer could very well have a large number of price lists printed, knowing that they would not only prove of considerable service but would also last for a long time without any need of revision. Nowadays the number of sizes of mounts is only exceeded by that of the various colours and substances in which they may be obtained, while the processes are so numerous, and in some cases so nearly resemble one another, that even photographers themselves are unable to say offhand in what process a print has been made, as, for instance, to quickly distinguish a good collodio-chloride print from a carbon. Under these circumstances the price list must necessarily be

differently compiled. Much must be left to local circumstances of which the photographer himself should be the best judge, but whatever is done the list should, by its general "get up," be a credit to the studio. This cannot be said of the majority of photographers' price lists—even where no glaringly inartistic effect is presented, they are frequently plain and unattractive to a degree, instead of being such that they compel attention by reason of their tasteful appearance. Such a list is that which was recently issued by a photographer in a Midland town for his Christmas trade and which is well worth description here.

#### A Model Booklet.

It has a cover of art paper,  $4\frac{1}{2}$  by  $2\frac{1}{2}$ , in the shade which the ladies describe as "crushed strawberry," and printed in black ink relieved by a small design in bright red. "Artistic Portraiture," "Especially for Xmas," and the name of the studio, is all that appears on the cover. The body of the booklet consists of four pages about a quarter of an inch less each way than the cover, which thus overlaps all round, and is stitched with thin silk cord. On the first page is the note, "A personal photograph is a Xmas gift always appreciated." The second page strikes the seasonable note again, "Artistic photographs in special covers designed for Xmas," and "A charming series of new designs in private greeting cards with your own photograph specially taken or copied"—in each case prices being given. The third page runs, "Many prefer to use the photograph mounted with the usual large margin at present in favour," followed by the prices thereof, and "Circular midgets finished in a sepia tone and mounted to harmonise." The fourth page quotes prices for pendants and locketts and has a note, "The morning light is preferred for a sitting during the winter months. Studio always kept warm and comfortable in cold weather." A headline across the middle pages runs, "Electric-light portraiture on dull days or at night," while a similar line at foot gives the name and address. The booklet is admirable alike in conception and in execution. By its pleasing appearance it attracts attention which it sustains by its unusual presentment of matter of seasonable interest.

#### The Need of Variety.

It may, perhaps, be thought that some injustice is done to the photographer who issued the above-mentioned booklet in so closely describing it, but such is not the case, as there is not the slightest doubt that, having displayed the possession of so much originality in its production, he will be quite capable of issuing something totally different when next he puts out a price-list. As with the Athenians of old, the public is ever thirsting to hear some new thing, and, frequently lacking the desired novelty wherewith to satisfy it, the photographer must perforce utilise new methods of describing what he has to offer

—in other words, he must vary the appearance of the price-lists and other matter sent to his prospective patrons. To many photographers this statement of the necessity for the adoption of the most modern commercial methods by the profession may seem exaggerated, but the fact that the most successful studios to-day are those whose proprietors are good business men—for such can generally obtain capable operators—is sufficient proof that the man who is working on a smaller scale should endeavour to combine up-to-date business methods with whatever amount of professional skill he may possess.

#### Circular Letters.

The circular letters which most photographers have occasion to issue from time to time generally admit of much improvement. Alike in their style and the way in which they are printed, they too frequently resemble the small tradesman's letter, which "begs to inform the nobility, gentry, and clergy of the surrounding district, etc., etc." The "script" type, which the average printer invariably uses for such letters, must be avoided, typewriting type, especially the "ribbon-face" in which the dotted effect of real typewriting is closely imitated, being by far preferable. Instead of the "Dear Sir or Madam" commencement, an estimate should be made of the probable number required of each, so that, at a slight extra expense, the printer can do a certain number with "Dear Sir," and the remainder "Dear Madam." If the usual note-heading be printed in black and the letter itself in purple, the greater part of the recipients will read it as an ordinary letter, and pay more attention to its contents than they would if they thought they were only reading an ordinary circular. For the same reason it is better to post in sealed envelopes with penny stamps, than at the open communication halfpenny rate.

#### The Question of Expense.

It may be objected that penny postage doubles the expense at once. It does, and so also may a high-class piece of printed matter cost twice as much as a poorly-printed one, but the point to bear in mind is that the purpose in view is not merely to inform people, but rather to so firmly impress them that results in the shape of sittings may follow. Any outlay in printed matter must therefore be measured by the business accruing therefrom, as well as by the amount of money expended, and it is obvious that if with twice a given outlay six times as much business is obtained, the bigger expense is the more profitable of the two. If, which is very likely to be the case, the sum which can be spared is limited and the expensive issue apparently impracticable, instead of saving on the quality, it is far better to cut down the number sent out by careful discrimination in making up the list of names of the addressees.

W. J. CASEY.

## THE SZCZEPANIK BLEACH-OUT PROCESS OF COLOUR PHOTOGRAPHY.

[The Austrian inventor, Herr Jan Szczepanik, has been announced for some time past to have been occupied in perfecting a sensitive bleach-out tissue for the printing of coloured images at one exposure from transparent coloured originals. The drawback to such processes in the past have been the extreme slowness of the tissue and the comparative impermanence of the copies, but Szczepanik's method appears to be approaching a commercial stage, inasmuch as the tissue is to be manufactured by Dr. J. H. Smith and Co., of Zurich, by whom provisional instructions for its use have been drawn up. We cannot better explain the application of the tissue than by translating the major portion of these directions.—Eds., B.J.P.]

THE paper is made in two varieties, black and dark grey. The latter paper is more sensitive and is intended for printing from soft originals, whilst the deep black papers are less sensitive and are to be used in the copying of oil paintings or such reproductions of

natural objects where there are great contrasts of colour. It requires to be printed in direct sunlight. Both papers are treated in exactly the same way.

#### Sensitizing.

The paper consists of three coloured films, each of which is capable of being completely bleached. The uppermost film—red gelatine—becomes insensitive some days after the preparation of the paper, which must therefore be used quickly—within 24 hours—after sensitizing. If the paper is not employed within this period, it can be resensitized and can be used as well as in the first case. This red film is sensitized by a short immersion in a special bath purchased with the paper. During the process the film must be kept in motion just as is done in developing a plate. After five minutes, it is taken out of the bath, any streaks removed, and laid between filter paper. By one or two strokes with the flat of the hand the superfluous moisture

is made to pass into the filter paper and the sensitized paper then taken up and left to dry in a dark corner of a room by free exposure to the air, and until the surface has lost all tackiness, as shown by applying one finger to a corner of the paper. The filter paper used for drying can be employed over and over again. Drying usually requires about 15 to 30 minutes. It should not occupy more than one hour and should not be conducted at a higher temperature than 70 deg. Fahr. The sensitizing is done by ordinary light of a room. The sensitizing solution is returned to the bottle after use and carefully protected from access of light and heat. About 250 c.c.s. will sensitize eight to ten sheets, 18 x 24 cm. (= 7 x 9½ inches).

#### Printing.

The paper may be printed in two ways:—

a. Direct printing from coloured original such as a hand-coloured lantern-slide, pictures in natural colours on glass, paper, and prepared by such well-known processes as those of Sanger Shepherd, Lumière, Rotary, Smith, Selle, Hoffmann, etc.

b. Printing by the Szczepanik method from the three monochrome positives.

In the first case, when there is a transparent coloured original to work from, the process is as easy as taking a print on P.O.P., the coloured print being placed in the printing frame and the sensitive paper exposed in contact with it in sunlight for 15 to 20 minutes. The process can be interrupted several times and continued by repeated exposure. When the printing involves no special difficulties the beginner is recommended to prepare one or two prints from the coloured pictures made on films and enclosed in every packet of the papers. In laying the bleach-out paper on the films the latter should be placed with the glossy side in contact with the paper as the colours of the film are not quite fast to light.

Immediately after the commencement of the printing the colours of the paper commence to bleach and a picture begins to show up on a dark background, on which, at first, the colours are only faintly seen, becoming gradually more and more brilliant. If exposed too long the print loses in strength and appears then more as a soft picture with scarcely discernible colours against a light background.

The properties of the upper film of red makes it necessary that the paper should be exposed at least at first to direct sunshine, so that the red film may bleach completely out. If this is done the rest of the time may be given in diffused daylight or in artificial light, the duration of the exposure being dependent on the intensity of the light. Freshly sensitized paper, after bleaching out the red image, must be protected by a piece of red glass on removal from the printing frame into the light in order to arrest the further bleaching of the red image. If this point is not attended to the red image will very likely be totally deficient in the print and the results, green only.

Compared with ordinary printing-out papers the sensitive paper is very slow, a defect which can be turned to advantage in arresting the process in parts of the image and thus producing colour effects at will.

The paper reproduces colour for colour, and with this fact in mind a hint may be given how coloured originals may be corrected in copying and better results obtained on the bleach-out copy than in the original. Since the red parts of the original give red in the copy, the use of a red screen will be understood to retain the red all over the image. The same action takes place in the case of the other colours, and thus a given tint can be given to the copy or the defect of a coloured original made good. For example, if a three-colour transparency is too blue, it is necessary to print the blue more than the red and yellow, and therefore the frame is covered with an orange screen which protects the red and yellow and allows only the blue to print.

#### Fixing the Prints.

The finished prints should be treated to repeated baths of benzole till the smell of aniseed has disappeared, and this takes at least twelve hours. The best plan is to leave the prints in the benzole bath all night. When dry, the prints should be immersed for about five minutes in the fixing solution, and then washed and dried.

The stability of the prints to light is somewhat limited. It is advisable therefore to protect them from sunlight and very bright light, or otherwise, even with the most careful fixation, they will soon lose their brilliancy and depth of colouring. In the light of an ordinary room the prints will keep for a very long time.

#### Finishing the Prints.

It is advisable to mount the prints before they are absolutely dry, as later, when they get too dry they may roll up and crack.

The print should then after fixation be superficially dried between filter or blotting paper, then brushed over with mountant and mounted in the usual way.

With good monochrome negatives and a little care and experience it is actually possible to obtain colour rendering true to nature. With natural coloured prints there can be no retouching. Through carelessness, prints may be obtained which will leave much to be desired in many respects. The improvement of individual places, such as spots or lines, can be very easily effected by applying the colour that is wanting, red, yellow or blue, by means of a brush to the absorbent gelatine film. Günther's transparent colours, which are used for colouring transparencies, are suitable for this purpose.

#### Szczepanik's Patent Printing Process.

It is assumed that the reader is acquainted with the theory of the so-called three-colour process which requires a set of three negatives, say prepared on Dr. Smith's patented three-colour plates, which permit of the three negatives being obtained with one exposure in any ordinary camera, or made on panchromatic plates with three exposures through the three corresponding colour filters. It will only be stated here how the colours of nature which are reproduced in the three negatives, can be produced on paper by a direct printing process.

For direct printing on the bleach-out paper, negatives cannot be used, for in this process where the light acts a bright colour is formed, that is to say, one lighter than black, so that from a negative a negative will be obtained. It is therefore essential to use a positive if a positive is required. Monochrome transparencies must therefore be prepared from the three negatives, each of which represents one of the three fundamental colours, red, yellow or blue. In order to avoid mistakes it is advisable to mark the plates with a letter, r, y, or b.

All three positives must be clear, rich in half-tones, and not too dense, and must be protected with a thick varnish of 6 per cent. collodion. Without this varnish, transparencies, when placed in contact with the bleach-out paper will immediately become yellow and therefore totally useless.

In order to make a print on the bleach-out paper it is necessary that the red transparency should only print on the red film, the yellow on the yellow film, and the blue on the blue film. The red must be printed first, as the red film soon loses its sensitiveness after sensitising.

The transparency for red is placed in the printing frame in contact with the paper, or with specially prepared glass if the picture is to be on glass, and so that the image shall only print on the red film it is necessary to cover the printing frame with a colour-filter, which only transmits those rays which bleach out the red and do not act on the yellow and blue films. In other words the filter must only transmit the green rays which are absorbed by the red dye, but reflected by the blue and yellow dyes. The printing frame must thus be covered with a green filter.

The rule is, The monochrome transparency must be printed under the complementary colour filter.

After printing the red positive, which will be recognised by the edge of the paper appearing a bright green, the picture will be seen in black on a green ground. The printing of the yellow is then proceeded with. The transparency representing the yellow is then superimposed on the image already obtained so that the outlines of the two absolutely coincide, and then this is printed under a violet filter till the edge of the paper shows a pure blue, and the picture is seen in orange on the blue ground, but also in some compound colours.

Finally, the blue plate is printed under an orange filter. This must be printed till it accurately corresponds, as regards density, with the yellow and red images, and this can be best controlled by frequent examination.

Special stress must be laid on the fact that the colour filters used in printing must be specially prepared for this purpose; they may be obtained commercially.

Should the print show any predominant tint this may be reduced by printing under the corresponding plate. If this tint is very faint it will be quite sufficient to expose the print under the corresponding filter.

With a little care the three transparencies may be alternately superimposed on the paper so that the outlines may accurately coincide in an ordinary printing frame, but special printing frames, which may be obtained commercially, will make this much easier.

The transparencies may obviously be enlarged, and therefore enlargements in colour may be made in precisely the same way as previously described.

## SULPHIDE TONING OF SILVER PRINTS.\*

THE toning of silver prints is generally understood to be accomplished with some preparation employing chloride of gold as the actual toning agent, the use of platinum salts being quite exceptional. In many of the so-called combined toning and fixing solutions where chloride of gold enters into the combination the actual toning takes place by the sulphurisation of the image, the gold remaining in the original solution, which can be extracted after the combined bath ceases to act.

Sulphide toning is a very different thing when compared to the effects of sulphurisation brought about by the complicated action of the combined bath.

Sulphide of silver is a very permanent substance, and photographs can be produced in pure black sulphide of silver by a special process, where collodion forms the basis, and the developed image converted into sulphide of silver by an after process. It must have been noticed by many amateurs that the whites of so many prints are degraded, and present a sickly greenish yellow appearance, when they have been toned in a combined toning solution containing many deleterious substances.

### Fixation Before Toning.

For sulphide toning the hyposulphite of soda solution must be much greater in strength than for use under ordinary circumstances, for in this case the fixing of the print takes place before toning, and success will depend very largely upon perfect fixing and thorough washing after fixing. The precautions to be taken are but few, but they must be carried out in a thorough manner.

The printing may be carried out the same as usual, about two shades darker than required for a finished print. Of course, a slight reduction of the image will take place during the fixing operation. Make up the fixing solution as follows:—

Hypsulphite of soda .....	4 ounces.
Filtered water .....	20 ounces.

As soon as the hyposulphite is dissolved the prints may be taken and plunged into the solution without being washed. As soon as all the prints are immersed, keep them in motion for ten minutes, so that the image becomes completely fixed; remove the prints, one by one, into clean water, or, better still, place a print upon the hand, rinse it well under a stream of water from a faucet, back and forth, then place it in a tray of clean water. Continue this operation until all the prints have been treated the same way, then, after rocking for a short time, change the prints again into another tray of clean water. This should be done eight or ten times. The prints may then be washed in running water for another ten or fifteen minutes. The object of this thorough washing is to free the print of every trace of hyposulphite of silver.

### The Sulphide Toning Bath.

As soon as the washing of the prints has been accomplished, make up the following toning solution:—

Filtered water .....	40 ounces.
Sulphide of ammonia (hydrosulphuret of ammonia) .....	10 drops.

Do not exceed twelve drops of this substance. Stir the mixture with a strip of glass. Toning may now proceed by placing the prints in the solution. Keep them moved about by rocking the tray and turning the prints over well—one over another. After a short time the prints will commence to change colour, first to a rich brown, then through the various shades to purple. Do not carry the toning too far; stop a little short of the colour desired, because prints that are toned by this method will dry down much darker.

As soon as the desired colour has been reached, place the prints in clean water, give them a few changes in clean water, from tray to tray, then about ten minutes more in running water. They are now finished and can be trimmed and mounted the same as ordinary prints. It will be found that the colours obtained are very much like gold-toned prints. Rich in colour, sometimes almost black, these prints will not fade. They are produced in true sulphide of silver. The hypo. fixing solution must be made fresh every time; if it is used twice, the probability is that the whites of the prints will suffer. The sulphur toning solution, too, must be thrown away as soon as toning is complete. This toning solution is probably the cheapest that can be made, the cost being about one cent per gallon.

### Causes of Failure.

If the paper used to make the prints on is at all discoloured, then it must not be expected to secure good, brilliant prints. If the white should become degraded, then the cause may be looked for in defective washing. If there is a trace of hyposulphite of silver left in the print, it will become reduced in the toning solution. The operations are not at all difficult nor tedious. Those who have never attempted this kind of toning will be surprised at the result, and if attention is given to the details described, there will be no fear of being unsuccessful. It may be well to mention here that the hydrosulphuret of ammonia is a somewhat offensive smelling liquid and should not be poured from its bottle except by drops directly into the water to be used as the toning bath. No doubt the sulphide of sodium might be used, or the sulphide of potassium, but the proportions of these salts would have to be worked out for successful working, while the proportions for working with the hydrosulphuret of ammonia have been carried out successfully.

### Sulphide Plus Gold Toning.

In connection with sulphide toning may be mentioned the fact that after a paper print has been toned in a gold toning solution, fixed in hyposulphite of soda, washed and dried, it can be retoned to a variety of colours, especially the rich purples, by semi-sulphur toning, in the following manner:—

A combined toning bath will be required, which can be made up by any one as follows. The chemicals should be dissolved in hot water the total quantity of water being 40 ounces:—

Hypsulphite of soda .....	1 pound.
Sulphocyanide of ammonium .....	6 drachms.
Citric acid (crystals) .....	2 drachms.
Powdered alum .....	2 drachms.
Nitrate of lead .....	1 drachm.
Acetate of lead .....	1 drachm.

Dissolve the above ingredients in separate portions of water, then mix in the order given; lastly dissolve six grains of chloride of gold in two ounces of cold water and add to the mixture; stir the mixture well; keep it under cover in a small stoneware jar or pitcher until quite cold; it is then ready for use. Pour into a clean tray about sixteen or twenty ounces of this mixture, then take the prints that have been previously toned and fixed, plunge them one at a time beneath the liquid, without previously wetting them. In a short time the colour of the prints will be seen to change. Keep them in motion, so that the retoning will be uniform. Stop the toning the moment the desired colour has been reached, by plunging each print into a tray of running water; wash the prints for about fifteen minutes, then lay them out to dry, back down, upon clean blotters, or, if they have been previously trimmed, they may be pasted and mounted upon the desired mount, carefully rubbed down and dried.

The writer has prints made upon printing-out porcelains toned in this manner six years ago. The colour has not changed in the least. The image seems to be a compound of gold and sulphide of silver. When porcelains are retoned the action in the above solution takes place rapidly.

This combined toning solution may be used over and over again for about six times, if a large number of prints are not treated each time it is used.

When the solution is first made up it will be noticed that there is a precipitation of sulphur; this may be kept in a wide-mouth bottle, and the clear liquid poured off when required for toning. There appears to be an advantage in allowing the precipitated sulphur to remain, although it must not be allowed to deposit upon the prints.

It is quite possible that the combined toning and fixing solutions that are made up for sale at the stock dealers will answer the purpose, but for those who desire to become acquainted with the chemicals they use, the above formula has been given. There is at all times a certain amount of pleasure in preparing the various compounds that are to be used in photography, and, having prepared them, to observe the action that takes place. This gives satisfaction and aids in fixing the cause and effect upon the memory. It also makes the operator far more proficient than is he simply buys everything he uses ready prepared. Then when work has to be carried out upon a larger scale, should difficulties arise he is competent to cope with them, which is not the case with those that at all times purchase ready-made articles.

A. J. JARMAN.

\* A paper in the "Camera and Dark Room."

## FOREIGN NOTES AND NEWS.

**Bichromated Gelatine.**

M. LUMIERE and Seyewetz have continued their researches on the above, and this time have investigated the insolubilisation of the same in the dark. The conclusions they come to are that it contains much less sesquioxide of chromium than that which is rendered insoluble by the action of light, and that the quantity of this salt increases very slowly, for after one month it amounted to only 0.67 per cent., and 1.15 per cent. after six weeks, whilst after a few hours exposure to light it amounted to over 5 per cent. Further, bichromated gelatine which becomes insoluble in the dark does not, even after  $4\frac{1}{2}$  months, completely withstand the action of hot water. If the bichromated gelatine is kept at 120 degrees C., boiling water will no longer attack it, but the gelatine becomes disintegrated and breaks up into small particles, which will pass through a filter.

**A Peculiarity of Drying Gelatine.**

R. E. Liesegang calls attention to a peculiar action of gelatine and accidentally of collodion, which, so far as we are aware, has not hitherto been noticed. A mixture of equal parts of a 10 per cent. solution of gelatine and 10 per cent. solution of potassium bichromate was coated on glass and dried; after two days the salt had crystallised out on the film in the well-known tree-like form. The plate was then well washed, but the gelatine itself showed the tree-like markings. Other salts showed the same results. The crystals are not evenly distributed for the extreme margins, for about five millimetres breadth, showed no crystallisation, although the yellow colouration proved that they contained bichromate. This phenomenon appears with other preparations, such as silver chloride printing-out plates, and the author asks, "Why are the margins poorer in salts?" If the edges dry before the middle of the plates, does the water in the damp parts extract the salts from the neighbouring drying parts, although the damp parts may themselves be saturated with salts? Liesegang ascribes this to a peculiar action of the drying gelatine, that is to say, the salts are pressed out of these parts, and states that with collodion precisely the same action, which is not a pure diffusion process, takes place, for with all collodion papers gradually the whole of the soluble salts and acids are "pressed out" into the paper support. [The note on "Marginal Fog," see our issue of December 22, 1905,

p. 1008, should be read in connection with this subject.—Eds., B.J.P.]

Liesegang states that if to a washed collodio-chloride emulsion some soluble chloride be added and coated on glass after a few days the whole of the silver salts have "wandered" from the collodion film, which is perfectly clear and silver free, and that they are imprisoned between the glass and collodion. A collateral experiment with barium platino-cyanide suspended in collodion or celluloid varnish for making a radio-active screen, showed exactly the same phenomenon. That this is not one to the sinking of the heavy particles of the salt is proved by the fact that exactly the same thing occurs when the position is reversed, that is to say, when the collodion film, after setting, is placed face downwards.

**Catalytic.**

Dr. Gros, who, in conjunction with Dr. Ostwald, patented the above process, contributes to the current number of "Das Bild" some interesting notes on this subject, and says that catalysis is the change in the rapidity of a chemical reaction produced by a substance which does not itself take part in the reaction though it may be affected by a secondary action. A well-known example of this is, of course, hydrogen peroxide solution and platinum, for the addition of the latter at once causes a copious evolution of oxygen. The quantity of platinum required to produce this action is extremely small, for if to 1 c.c.m. of a 1.50 normal solution of peroxide 0.000,003 gm. of colloidal platinum be added, the whole of the oxygen is given off in three hours. An analogous case occurs with a mixture of chlorine and hydrogen, the addition of 0.1 milligrammes of colloidal platinum to 50,000 times the quantity of  $H + Cl$  produces chemical combination. If this fact be true of catalytic agents, then it should also apply to anticatalytic agents, and Gros finds that minute additions of iodine, mercuric chloride, sulphuretted hydrogen, hyposulphite, or hydrocyanic acid will act as anticatalytic agents, and that the addition of 0.000,000,001 gramme of hydrocyanic acid per cubic centimetre will reduce the catalytic action of 0.000,006 of colloidal platinum to one-half. We have heard but little of the practical applications of catalytic, but Dr. Gros suggests that we have in these "anticatalytic" salts powerful agents which will make the process of more practical value.

## ELECTRICITY v. GAS AS A SOURCE OF HEAT.

The heating and lighting of premises are questions to which a photographer has to pay constant attention, and, like anyone else, he must consider them together. The two sides of the matter will probably appeal to our readers more directly than to those of a general paper, and therefore we quote at length from a well-considered discussion of the question recently published in the *Globe*. The points raised may assist those about to change their system of lighting and heating as to which source of these commodities they shall adopt.

Electricity for lighting, if it has not been the rival of gas which was anticipated a few years ago, is certainly gaining ground steadily, and there is little doubt that its advent into the field of illumination has stimulated the gas companies to improvements and developments which, but for the healthy exercise of competition, might never have come into being. When we come to another department into which electricity has quite recently begun to assert itself, the domestic category of cooking and heating, the pros and cons of the rival agencies are not so clearly defined, and if the exhibition held a month or two since at Olympia has served to increase public interest in the possibilities of electricity, it has also induced the gas companies to examine into the claims of their electrical competitors, and, not unnaturally, to come to the conclusion that gas is an easy winner in the race for popular favour.

**Electric Prices for Heat and Light.**

It is not our business to hold a brief on the one side or the other, but having regard to the fact that the Gas Light and Coke Company

have gone to the trouble of issuing an interesting circular on the subject of cooking and heating we have thought the subject of sufficient importance to obtain the views of some of those qualified to answer for the electric lighting companies on the points raised, and incidentally to clear up certain questions which will naturally have occurred to anyone who, having electricity in the house, has contemplated the possibility of adapting it to newer uses. And on this matter we may say at once that no very convincing explanation is given by the electric lighting companies of the great disparity in the price per unit for lighting and cooking respectively. It would surely be to the interest of the companies to bring the charges into nearer relation; either that for lighting is too high, or the price charged for cooking is absurdly low.

**Usable Heat.**

In the circular to which we have referred the gas company very rightly makes a strong point of the cheapness of gas both for heating and cooking compared with electricity. Six cubic feet of gas, costing one-fifth of a penny, will give as much heat as a unit of electricity, the lowest price quoted for which, for the purpose under discussion, is one penny. The answer is not without its own force. Freely admitting the accuracy of the figures quoted, and preface the reply with the debating point that the anxiety of the gas company to place its case before the public is an acknowledgment of the growing competition of electric heating, health and efficiency are the heads under which the electric lighting companies take their stand. The six

cubic feet of gas may give as much heat as a unit of electricity, but they ask how much of it do you get? In nearly all cases (and if not all the health consideration comes in with increasing force) gas fires are provided with chimneys leading into the fire-places in which they are situated, with the result that a large proportion of the heat, even with the best and most modern stoves, finds its way up the chimney, the loss being stated at what is declared a moderate estimate at between 50 and 60 per cent.

Gas stoves were, of course, first in the field, being welcomed for just those reasons which electricity can adduce with the health advantages as a set-off against the greatly increased price. The gas fire is cleaner than the coal, saving dust and obviating labour, but it cannot, it is contended, make any claim to being a healthy means of heating a room. In the best circumstances, it uses up an amount of oxygen which soon produces an appreciable dryness in the atmosphere, and the acetylene fumes so often given off when coal gas is burned with an insufficient supply of air are, of course, poisonous and produce the effect of a narcotic. No one who is in the habit of using gas fires can be unconscious of such conditions, or of that trick of "firing back," as it is termed, which produces the fumes already mentioned. Granted we are more expensive, says Electricity, but considering that our efficient heating is so much greater than gas, with its immense chimney waste, and realising that if we dry the air, as we needs must, we neither draw off the health-giving properties nor pollute the atmosphere, we hold that we give a better article, if a dearer one. Price must have its influence, but quality, alike in the capacity to do fully what a unit pretends to do, and in the innocuous character of its operations, argues Electricity, must surely be put against the cheapness of the six cubic feet.

#### Heat Without Fire.

As to the sentimental aspect of the question—the gas company asserts that "few people have been found to try as a source of heat an apparatus that bears no resemblance to a fire"—Electricity is inclined to treat the point as a trivial one. There is the luminous radiation and there is the non-luminous one, and Electricity holds that it looks quite as cheerful in its former capacity as do many of the long lamp-like chimneys of many a gas heater, while it declares that the only gas fire which does bear some resemblance to the cheery original, the asbestos bits in the open grate, is at once the unhealthiest and the most expensive in its consumption of cubic feet.

#### Electric Heating.

Concerning the electric cooking stoves, it is admitted they are still in the experimental stage, out of which the gas cooker itself has only for a few years emerged, but this period we are optimistically assured will be speedily passed; rapid improvements are being made, and it will quickly demonstrate its practicability for general use as well as for special cases. Many of the leading restaurants now have a complete plate-heating service installed in the buffet and dining rooms. It is admitted that owing to the various patent rights in the electrical apparatus the prices are expensive, and to some extent prohibitive, but we are assured that so soon as the manufacturers of this apparatus are enabled to reduce the price the adoption of electricity for cooking purposes will greatly increase. Such companies as the Charing Cross and Strand Electric Supply and the Chelsea Electric Supply—to mention only two out of many—lose no opportunity of demonstrating the many domestic uses to which electricity can now be applied.

And this brings us finally to a consideration of the conditions of the domestic supply of electricity. The competition between the gas and electric lighting companies cannot fail to interest the public, for a wholesome rivalry means in the end efficiency and cheapness. The question naturally arises why the electric supply companies can offer the power as low as a penny per unit for cooking and heating purposes, while for lighting the cost is so much greater. The answer is that the bulk of the supply for cooking and power is used at the hours of low load, and that it pays to charge a price which is barely cost. Where electric heating is employed, and is carried on for eight hours a day, it constitutes what the companies term a very good load factor. If electricity for lighting purposes was used at all hours of the day, it could be supplied, we are told, at approximately the same figure as for cooking, but having regard to the fact that there is no restriction as to the cooking hours—and, obviously, none would be possible—we

still maintain that the difference between, say, one penny a unit for cooking and sixpence for lighting is unconscionably great. As meters and wiring, it is explained that in the case of power for cooking and lighting double wire is necessary, as the copper needs to be of greater capacity for cooking, heating, and power than for illumination. The current used can be measured in two ways—either by a double tariff meter, charging a certain rate at hours of high load, and a lower one for the period of low load, or the separate circuits can be separately metered. The latter is the more prevalent practice.

## Photo-Mechanical Notes.

### Penrose's Annual.

We process workers—all of us that can afford it—make a point of getting our "Penrose's Annual" year by year, and I should be sorry myself to see the continuity of the volumes on my shelves broken at all. Thus a lengthy review should not be necessary to readers of these Notes: but my object is to draw special attention to some items in the volume which appear of special importance to the photo-engraver. A mention of them should shew him—if he has not the volume—the extent of its value to him.

The cover has on it a three-coloured modelled design. It does not strike one as particularly artistic; some of the modelled effect is bound to be lost when it is coloured, and though it is a *tour-de-force* to print three-colour on the cloth itself, this is not going to wear at all well; already the picture is half worn on my own copy.

Generally, the type, ornament, and get-up of the book are pleasing, but some of the colours in which many of the blocks are printed are, to my mind, extremely unpleasant, and do more at all do the work justice.

Among the ordinary half-tones the example of catalogue work are the most striking, those hailing from America being the best of these.

Of the three-colour plates, André and Sleight's vase and reproduction of a painting by McWhirter stand easily on top; after this beautiful quiet and restrained colouring, most of the other colour work looks crude and garish. The reproduction by Mr. Zander's four-colour process, except in the rendering of the violet and green, does not look at all superior, in the copy I have, to the reproduction of the same subject by the ordinary three-colour process.

There is a capital reproduction of pencil by the Sear's "high light" process, though the statement that it is printed on rough drawing paper must not lead any one to suppose that it is printed on the surface as shown, because this roughness has probably been obtained by embossing after the printing. There is a good article on the way this process may be worked by Mr. Burton Norton.

Another very interesting supplement is the reproduction of portrait on four different papers by the wet-plate process, collodion emulsion, and dry plates. On the whole, the palm must be awarded to the dry-plate, the emulsion looking very hard and contrasted. There are some useful tables relating to exposures by "C. B." (Does the Prime Minister go in for "process" as well as photography?) and Mr. Branfill which should be kept at hand in every process camera room.

Finally, the workers in this craft ought to ponder the article by Louis Flader on "Some Results of Organisation." He speaks of the high position of the employee in America (where "the are the people," as an American once said to me), and he asks if we can now understand the astonishment of the American at the failure of his European brothers to organise. Certainly, it

view of the results they have attained, this astonishment is excusable.

I have left unmentioned many good things in the "Penrose's," and probably items which I have omitted will be more useful to some than those I have dealt with, especially to the collytyper and lithographer. But I have aimed at picking out a few of the contents of special interest.

HALF-TONE.

### Another Henschel News-sheet.

It was not to be expected that Mr. Henschel could resist the temptation to appear with a repetition (with variations) of the "Half-tone Times" during the General Election; in fact, it was evident that he was waiting his chance to combine again humour with advertisement. This issue of the Henschel periodical press shows him in a new though expected rôle—that of agent for the sale of photographs to the Press. His firm in Fleet Street holds stock of the portraits of celebrities and of those who may be celebrities any minute in these stirring times. The series is that of Elliott and Fry, and the worried editor will doubtless turn for a portrait to reproduce where he can get both block and licence at one operation.

### A New Paper.

In a recent number of the "Photographisches Wochenblatt" was given a colotype supplement, printed on a "bromsilberimitations-karton," made by Beneke, of Löbau, Saxony. This paper is a novelty, and in consequence of its great absorptive power it sucks the printing ink up so thoroughly from the plate that it gives the most delicate details with a richness in the shadows, and further enables the very finest grain to be used. The result is certainly extremely satisfactory.

Among the patent applications of last week appear those of:—John William Ippers, 65, Chancery Lane, London, for improvements in photo-mechanical printing (26,695); of Klimsch and Co., Frankfurt, Germany, for improvements in the manufacture of photo-printing blocks (No. 27,158).

### MR. WALTER BARNETT IN AMERICA.

MR. H. WALTER BARNETT, of Knightsbridge, London, is at present the guest of J. C. Strauss, of St. Louis, and has an exhibit of his photographs at the Strauss Studio, Grand and Franklin Avenues, St. Louis, Mo.

This collection contains photographs of royal and titled English men and women, printed in mezzotint and on flexible mounts.

According to the "P" otographer, Mr. Barnett has departed from the English conventional photographs. He has produced something broad and daring, and yet he has faithfully portrayed the English type and character. He has given life and individuality to his sitters, which is not the accepted form of English photography.

"Americans lead in the art," said Mr. Barnett. "And it is because the people of America are eternally demanding something new. In England the people are conventional, and cling to established rules."

"Every Englishwoman wants a portrait representing her to have perfectly arched eyebrows, a Cupid's-bow mouth, a straight nose, and a slender form, whether she possesses them or not. If a photographer is successful this is the sort of photograph he must turn out. That is why all the photographs of Englishwomen look alike."

"In America women like to be made beautiful, yet they want independence and individuality, which gives to the photographer much liberty for bold, broad work."

"In my work I have refused to give these namby-pamby doll-like portraits, yet I have been forced to retain to a greater or less degree the conventional forms."

"I admire the daring and boldness of the high-class American photographers. They say Americans are lacking in the artistic sense, that they are purely commercial; but I cannot believe it. They must have the artistic sense, else they would not accept the characteristic work of their photographers. I look for the highest development of art in America."

From the catalogue of Mr. Barnett's exhibition, which reaches us from St. Louis—we see that the collection of exhibited photographs numbers 118, and includes a great many of leading members of the English aristocracy, "Personages of Prominence and Title in London Society"—is their designation on the catalogue, and the names alone are sufficient to bring a crowd of visitors to Mr. Strauss' studio.

### ROYAL PHOTOGRAPHERS.

THE "London Gazette" of January 2 gives the list of tradesmen who hold warrants for various Royal personages, and who thus have the right to use the Royal Arms. The photographers holding warrants of appointment to His Majesty King Edward VII. from the Keeper of the Privy Purse, with authority to use the Royal Arms, are:—J. B. Ciolino, Frankfurt; W. and D. Downey, London; J. F. Langhans, Prague; Arthur Marx, Frankfurt; Carl Pietzner, Vienna; Russell and Sons, London; and T. H. Voigt, Hamburg.

Those holding warrants of appointment to His Majesty from the Lord Chamberlain, are:—Hills and Saunders, Eton; Thomson and Sons, London.

The photographers who are permitted to style themselves, "By appointment to the late Queen Victoria" entitling them to use the Royal Arms, are:—W. Abernethy, Belfast; T. and R. Annan and Sons, Glasgow; Brown, Barnes and Bell, Liverpool; Chancellor and Sons, Dublin; W. H. Grove, London; Gunn and Stuart, London; A. L. Henderson, Ponders End, Middlesex; Hughes and Mullins, Ryde, Isle of Wight; H. N. King, London; Lettsome and Sons, Llangollen; London Stereoscopic and Photographic Co., Ltd., London; R. Milne, Ballater; A. and G. Taylor, London; R. Welch, Belfast; and G. W. Wilson and Co., Aberdeen.

The photographic firms who hold warrants of appointment from the Lord Chamberlain to Queen Alexandra, with authority to use the Royal Arms are:—W. and D. Downey, London; Kodak Ltd., London; Lafayette Ltd., London; and W. S. Stuart, Richmond.

### ONE WAY OF GETTING BUSINESS.

A PHOTOGRAPHIC studio in Bournemouth is attracting business by a novel competition, particulars of which we obtain from an advertisement in the Bournemouth "Observer."

The specialty of this firm is to produce photographs on postcards by a rapid process, orders being executed and delivered while customers wait. The price of a dozen is 3s., and of a half-dozen 1s. 9d. The competition which has been arranged is a very simple one. Competitors are invited to answer two simple questions:—

There will be four classes, A, B, C and D, and three prizes will be awarded in each—12 prizes in all.

Class A.—Prizes will be awarded to the three persons who give the most intelligent answers to these two questions:—

(1) Why are people photographed?

(2) Why should people be photographed?

Class B.—A coupon competition. Prizes to the three persons who collect the greatest number of coupons attached to receipts given for daily orders.

Class C.—Introduction competition. Prizes to the three persons who introduce the largest number of their friends to the studios.

Class D.—Collecting card competition. Prizes to the three persons who collect the greatest number of photographic postcards of this firm.

One person may compete in all four classes and may get four prizes.

Only those who have been photographed at the studios may enter the competition.

Photographs on postcards while you wait, 6 for 1s. 9d.; 3s. for 12. Special sizes:—Cabinets, 4s. 11d. per dozen; carte-de-visite, 3s. 11d. per dozen; enlargements, 4s. each.

If you cannot personally attend, send your photograph and it shall be reproduced and returned with copies, post paid, at the following prices (on receipt of postal order):—Postcard photographs: 6 for 1s. 9d.; 12 for 3s.; 24 for 5s.; 100 for 15s.. Cabinets, 4s. 11d. per dozen; carte-de-visite, 3s. 11d. per dozen; enlargements, 4s. each.

The competition is apparently a weekly one, and the names of successful competitors are announced in the local newspapers.

#### A LECTURE-ROOM PROJECTION INSTALLATION.

A DESCRIPTION is given in a recent issue of the "Scientific American" of an improved projection system, designed by Prof. Eric Gérard, of Ghent, Belgium. The necessity for darkening the auditorium and employing an assistant who is liable to give rise to trouble by confusing the pictures has often been found to be a serious drawback. The Gérard system permits the projection of lantern-slides in full light and without the aid of an assistant.

The projection screen is a sheet of plate glass, nearly 4 ft. square, ground by means of a sandblast to provide a rougher surface than glass etched in the usual manner with acids. To avoid the necessity of darkening the room, a sheet-iron casing is provided which connects the screen with the projection lantern, thus inclosing the light

beams and cutting off any side light. The projection lantern contains a continuous-current arc lamp with a regulator, adjusted for 15 amperes and located at a distance of about 7 feet from the screen. The beam of light obtained under these conditions is sufficiently strong to allow the projected image to be seen transparently through the ground glass throughout an auditorium containing 300 seats, while the room remains lighted up.

In order to dispense with the services of an assistant in bringing the slides successively before the lantern, all the slides to be used in a lecture are arranged beforehand at the periphery of a wheel resembling a bicycle wheel. By means of a special gearing the wheel is set rotating with a crank situated below the screen, so as to cause the slides successively to pass through the lantern. The wheel can be turned backward and forward at will, so that any given picture can be reproduced over again. A switch placed beside the controlling crank serves to light the projection lamp.

#### THE AIM IN ADVERTISING.

LOOKING over last year's volume page by page the other evening we were interested in noting the number of contributions which have appeared on the methods and aims of advertising for photographers. We expect to have some more to publish on this topic, which we believe the professional photographer will profit by keeping before him, not necessarily with the intention of spending money lavishly on advertising, but of seeing that what he does spend is wisely expended. On this point we find some paragraphs in the current issue of the "British Advertiser" worth quoting:—

A merchant selling goods is an individual who is accommodating and conveniencing the general public by putting the goods or material which he sells within easy and convenient reach.

This same merchant, through the medium of advertising, tells the buyers to just what extent he can serve and provide for them in his

particular line—better than others, and therefore to just what extent he is entitled to their patronage. If he is really better able to serve the public and can convince the people of the fact, he will certainly get the patronage.

And right here is the point: good advertising is nothing more or less than good arguments—the seller argues with the people concerning his goods through his advertisements. An argument may be ever so beautiful, but no argument was ever effective that was not logical and did not appeal to reason and common sense.

If you state a strong point in an advertisement, give a reason, tell why it is so; then it is shown to be the truth and appeals to the reason; an unsupported statement that a thing is so is not convincing.

When a man is writing an advertisement for some one else and about something that he does not know a great deal about he is of course anxious to impress the public with his literary ability, so he sits down and thinks and thinks until his brain is in a whirl trying to evolve something witty, apt or original, but if it should ever happen that this same man should start to write an advertisement for himself it would come "a dawning" on him that what he wanted was the real points of excellence simply and convincingly stated and that he didn't want some far-fetched idea or catchy phrase that really carried no argument.

Different articles differ immensely in their good and strong points possessed, but there is no article but has its best or strongest point, and there is always a reason why this point exists, and this is the thing that should be brought out in an advertisement.

The first thing is to bring out the point that makes the article of real value to the buyer. Then price is absolute there is no contradicting it, and it possesses the merit of truth when used in an argument or advertisement.

The common sense point of an advertisement, the appeal to the reason of the reader and the showing why in real reason the thing must be so, is the kind of advertising that brings returns and not the literary effort or the airy flight of fancy.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between December 27 and 30:—

**SHUTTERS.**—No. 26,951. Improvements in timing valves used for varying the speed of time exposures of photographic roller blind shutters. John Croft, 7, Edgbaston Terrace, William Street, Birmingham.

**CAMERAS.**—No. 27,004. Improvements in photographic cameras. William Speed Hayman, 9, Regent Street, London.

**PRINTING FRAMES.**—No. 27,071. Improvements in photographic printing frames. David Abraham Lowthome, 70, Chancery Lane, London.

**TIME DEVELOPMENT.**—No. 27,078. Apparatus for timing development of photographic plates. Mario Fortiori, 18, St. Ann's Terrace, Barnes, London.

**PHOTOGRAPHS.**—No. 27,088. Improved process and apparatus for the production of photographs. Friedrich Grubius Dischner, 55, Chancery Lane, London.

**SHUTTERS.**—No. 27,125. Improvements in the method of operating the time and instantaneous shutters of photographic cameras. Edward Benjamin Hazleton, 103, Fitzwilliam Street, Sheffield, Yorkshire.

**PLATE CARRIERS.**—No. 27,219. Improvements in slides and plate carriers for photographic cameras. Frederick MacKenzie and George Wishart, 65, Chancery Lane, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CARTRIDGE TUBES.**—No. 8,971, 1905. The invention consists of a new description of tube to be used as a receptacle of chemicals. It consists in its simplest form of two small tubes of glass

celluloid or other suitable material closed at one end and joined together at their open ends by means of a cork or other stopper, which is provided with a narrow flange corresponding to the thickness of the tubes. After the tubes have been filled and then joined together, the joint is covered over and hermetically sealed by a strip of paper or other suitable flexible material and a suitable binding substance.

Fig. 1 of the drawing filed with the Provisional Specification illustrates a receptacle composed of two tubes *a* and *b* placed end

Fig. 1.

to end and closed by a cork *c* provided with a flange *c'*. *d* is a strip of paper, which may be simply gummed on one side and then applied over the joint, instead of which the joint may be first sealed with paraffin or other suitable material and then covered with a label.

Instead of forming two compartments as described, each holding a different chemical, the receptacle may form three or more compartments—that is to say, it may be composed of two outer tubes closed at one end and one or more intermediate tubes open at both ends, as indicated by Fig. 2.

Each intermediate tube is closed at the ends by a pair of stoppers, which connect the tube with the adjoining tubes, and

Fig. 2.

each flange or joint thus formed is covered over with a label or strip of paper or other suitable material.

Instead of providing the stopper near its centre with a flange or ridge, studs or pins may be inserted into its circumference, to serve as a stop or abutment to the tubes, and even plain cork stoppers (without any abutment) may be used, without departing from the invention. John J. Griffin and Sons, Ltd., and Thomas Pratt, 20-26, Sardinia Street, Lincoln's Inn Fields, London.

**STEREOSCOPIC CINEMATOPHGRAPHS.**—No. 4,423, 1905. The method of producing stereoscopic animated photographs for which protection is claimed consists of a combination of an instrument mounted on a pivot, a rotatable cam disc and stationary stop pieces adapted to abut against the cam disc.

One manner of carrying the invention into effect in connection with a cinematograph camera is shown diagrammatically in Figures 1 and 2, the complete instrument being pivotally mounted upon a suitable stand or support *b*. One convenient form of so mounting the instrument *a* is by means of a plate or bracket *c* secured with a stem or pivot pin *d* carried by the standard or support *b*.

Upon the spindle *e* of the operating handle *f* or some other rotatable part of the instrument there is fixed a wheel or disc *g* having a number of lateral cam-like projections formed around each side of it and adapted to engage or abut against stop pieces *h* fixed upon the aforesaid stand or support *b*. The stop pieces *h* are preferably provided with rollers to reduce friction and attrition. Rollers *i* are also provided for the support of the camera to facilitate the movement of the same.

On the rotation of the handle *f* in the usual manner to impart the required intermittent motion to the film, to effect the movements of the shutter and perform other ordinary functions, the aforesaid cam wheel or disc *g* is rotated, and during such rotation its lateral projections are brought into engagement with the fixed stop pieces *h* arranged on its opposite sides as aforesaid. As the cam projections push past the stops a sufficient force is

imposed on the instrument and the pivotal bracket on which it is mounted, to rock or reciprocate the same. The movement is arranged so that the views taken shall, as with a stereoscope, respectively correspond with the different views seen by the two

Fig. 1.

eyes of an observer. In the production of a series of pictures on a film, the instrument takes views alternately as seen by the

Fig. 2.

right eye and left eye of an observer. Each view is distinct and independent, but in its display, by means of an ordinary cinemato-

Fig. 4.

graph or projecting instrument, the rapid movements giving the well-known animated or life effects also serve to give the stereoscopic effect of solidity.

Instead of imparting a vibratory or reciprocatory movement

to the complete instrument, such movement may be given only to the lens of the cinematograph camera, or the like. In this modification the lens *j* is mounted upon a plate *k* (Figures 4 and 5) which is capable of sliding within suitable guides as *l* on the frame or standard *l*. The plate *k* may, if desired, be pivotally mounted upon the standard *l*. The required reciprocatory or rocking motion is imparted to the plate *k* by means of a cam *h*

Fig. 5.

mounted upon a spindle *m* rotated from the handle of the instrument. The said cam *h* is adapted to engage projections *h*<sup>1</sup> of the plate *k* or a aperture formed therein. By the slight reciprocatory movement of the lens during the operation of the instrument the same result is obtained. Harry Hamilton Moon, Park-field, Park Road, Moseley, Birmingham.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—  
Photographic Cameras, No. 24,803. La "Vega," Société Anonyme de Photographie et d'Optique.

#### FORTHCOMING EXHIBITIONS.

- January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.  
January, 1906.—The Dover Institute Photographic Society. Hon. Secretary, H. Plowright, 47, Maison Dieu Road, Dover.  
January, 1906.—Brierley Hill Camera Club. Hon. Secretary, J. Thomas, William Street, Brierley Hill.  
January 11-13, 1906.—Boston Camera Club. Hon. Secretaries, H. M. Hames and R. W. Halliday, 65, West Street, Boston.  
January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.  
January 25-27, 1906.—South Essex Camera Club. Hon. Secretary, Thomas Michell, 180, Browning Road, Manor Park, E.  
January 31, 1906.—Tring Camera Club. Hon. Secretary, J. Owen Raymond, Frogmore Road, Tring.  
February, 1906.—Windsor Camera Club. Hon. Secretary, Thomas J. Cartland, Thames Side, Windsor.  
February, 1906.—Cardiff Windsor A.P.S. Hon. Secretary, W. A. Woodward, 187, Mackintosh Place, Cardiff.  
February-March, 1906.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.  
February 3-10.—Cape Town Photographic Society International Exhibition. Entries close January 13, 1906.  
February 3-February 25, 1906.—Marseilles Fourth International Salon. M. Astrer, Sec. Gen., 11, Rue de la Grande-Armée, Marseilles.  
February 6-9, 1906.—Guisbrough Fine Art and Industrial Society. Hon. Secretary, George Page, 34, Westgate, Guisbrough, Yorks.  
February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.  
February 20-21, 1906.—Royal Albert Institute, Windsor. J. W. Gooch, Hon. Secretary.  
Feb. 22-24, 1906.—Bowes Park and District. Hon. Sec., H. C. Bird, 91, Whittington Road, Bowes Park, N.  
February 24—March 10, 1906.—Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 3A, N. St. David Street, Edinburgh.

February 24 to March 31, 1906.—Birmingham Photographic Society. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March, 1906.—Leicester and Leicestershire Photographic Society. Hon. Sec., W. B. Woodland, 18, Beckingham Road, Leicester.

March, 1906.—Rugby Photographic Society. Hon. Secretary, R. N. Myers, 13, Bridget Street, Rugby.

March, 1906.—Photographic Society of Ireland. Hon. Secretary, H. V. Yeo, 194, Clonliffe Road, Drumcondra, Dublin.

March, 1906.—St. Helens Camera Club. Hon. Secretary, John Glover, 14, Ormskirk Street, St. Helens.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 7-8, 1906.—Doncaster Camera Club. Hon. Secretary, T. Haigh Connor, 39, Market Place, Doncaster.

March 12-15, 1906.—Cripplegate Photographic Society.—Secretary, Fred. Leeks, 8, Barford Street, Islington, N.

March 13-14, 1906.—G.E.R. Mechanics' Institute (Stratford). Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone, E.

March 14-17, 1906.—Nottingham Camera Club. Hon. Secretary, S. W. Barlow Yines, Market Chambers, South Parade, Nottingham.

March 19-24, 1906.—Sunderland Photographic Association. Hon. Sec., William E. Kieffer, Stirling Street, Sunderland.

March 27, 1906.—Brentford Photographic Society. Entries close March 27. Secretary, Oliver Gluyas, 89, Windmill Road, Brentford, Middlesex.

March 31 to April 10.—Salon of the Photo Club of Nice.—Address the Secrétaire-Général, 20, Rue St. Francois de Paule, Nice.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

April 18 to 20.—Southend-on-Sea exhibition. Hon. Sec., J. Archer, 24, Ashburnham Road.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

## New Books.

"Intensifying and Reducing Negatives." (No. 74 of "The Photo Miniature.") London: Dawbarn and Ward, 6d.

This number is likely to be valuable and welcome, as it aims at bringing our knowledge of processes of intensification up-to-date, and deals very fully with the more important and reliable methods while relegating those of a more doubtful nature to quite a second place. The old methods which receive most prominent attention are mercury and ferrous oxalate, and silver intensification. This is just as it should be, for it is difficult to find any others approaching these two for reliability. The new methods of intensification by re-development receive very careful attention, and the editor remarks with reference to them, "Unless we are mistaken, these re-development methods will eventually replace the earlier and more cumbersome processes." In referring to the chromium process one or two unfortunate slips are made on page 57. Potassium chromate is repeatedly referred to, whereas we believe the writer intended to mention the bichromate in each case. Also there is a mistaken suggestion to the effect that the developer reduces the chromium compound to a black chromic substance. This substance is actually light brown, and though the redeveloped image is black if the process is only repeated once or twice, yet after many repetitions the brown substance accumulates to such an extent that the whole image becomes brown.

The writer, Mr. Thorne Baker, attributes the frilling occasionally

met with to the use of the acid bath in warm weather. We should rather attribute it to following the acid bath with an alkaline developer containing caustic soda. With a neutral or acid developer, such as amidol, frilling never occurs, and dilute hydrochloric acid alone has little tendency to produce frilling in any case.

A valuable feature of this chromium process (not referred in the book) is that it may be applied to a plate directly after fixation, as the presence of hypo in the films is of no consequence. This advantage it shares with the iodine processes, as mentioned by Mr. Thorne Baker on page 59.

Among the new processes dealt with we find a permanganate process, another with copper chloride, and one with iodine. The chromium process being undoubtedly the most important is very completely dealt with, and the author has quoted largely from the original papers published upon the subject. He has, in fact, wisely adopted this course throughout the book; hence we have the chromium process as described by Mr. J. S. Teape, and the chromium and iodine processes as described by Messrs. Piper and Carnegie. The mercury and ferrous oxalate method is described with full details by Mr. Chapman Jones, and the silver intensifier by Mr. A. J. Jarman, and by Mr. H. W. Bennett. Reduction methods take very little space. In describing the permanganate reducer the sulphuric acid has been left out, and therefore the instructions given are not likely to be very effective. The addition of 20 minims of acid to the stock solution will possibly put matters right.

"The Optical Lantern for Projection and Enlarging" (No. 28 of "The Practical Photographer.") London: Hodder and Stoughton, 1s.

This should be a useful handbook for the lanternist. The most valuable part of it is, perhaps, that relative to the use of electricity for illumination purposes, yet the practical advice is much sounder than the optical theory which is dealt with here and there. It is curious that so many erroneous ideas should prevail with regard to lantern optics, but it appears to be an unfortunate subject that suffers greatly from its friends. Among the old familiar errors that appear in this book, one is that the light source must be at the principal focus of the condenser to secure even illumination. Another is that a long focus projector gives a less brightly illuminated image than a short focus projector, "other conditions being the same," because the distance between lens and screen is greater; a very familiar example of the misapplication of the law of inverse squares.

Then, again, we are told that "the ordinary distance of the light from the condenser is two inches, but as the size of the disc decreases, it may be as far away as three inches. This applies to all forms of illuminant." Possibly "decreases" is here a simple misprint for "increases."

With regard to the use of the incandescent mantle many questionable statements are made. We are told that "the larger the source of light the more it blurs the definition"; that "the back of the mantle is of no use"; and that "only about half-an-inch of the mantle is used for projection."

A simple method of finding the focal length of an objective is given on pages 42 and 43, but as the method is not strictly accurate it is useless to work out the result to hundredths of an inch, as the writers have done. An approximate method can only give an approximate result.

The chapter by the editor on "Easy Introduction to Lantern Optics" treats optical questions in a much more accurate fashion, and forms quite a good elementary treatise.

The review of pictorial work is devoted to Charles H. L. Emanuel.

"Willing's Press Guide." The 33rd annual issue reaches our table from James Willing, Junr., Ltd., 125, Strand, and we notice that the established arrangement is adhered to in so much that the volume is as convenient a reference to the British Press as any three times the size. We should point out to the compilers that in their desire to be encyclopædic they include in the class list of periodicals "Journ. and Trans. of the Photographic Society," "Journal of the Royal Photographic Society," and "The Photographic Journal," as three separate entries, without any indication that they are one and the same publication. This is the only criticism we have to pass on the list of photographic periodical literature, which is other-

wise accurate and complete. The price of the "Guide" is 1s., and we would recommend its purchase to those persons who occasionally worry us to tell them which are the papers likely to buy their photographs (undescribed) for reproduction.

## New Materials.

Leto Toners. Sold by the Leto Photo-Materials Company (1905), Ltd., Rangoon Street, London, E.C.

These ready-made toning solutions for bromide and gaslight prints may be said to represent the operations of obtaining coloured tones on these papers reduced to the simplest proportions. The toning baths act, in every case, in one solution, which is made by mixing in equal parts two of the four liquid preparations and adding some water. Less trouble than this can scarcely be demanded, even in these days of leaving the photographer to do nothing but pour his solutions into his dishes. The prints tone evenly and quickly in the baths, and we have been pleased with the colours obtained. On a matt paper the effects are distinctly suggestive of those of carbon, and though we are strongly of the opinion that a photographer will be acting foolishly in representing the prints to be allied to carbon by the use of such words as "carbonet," yet the prints themselves will quite satisfy many who prefer a warm tone and a matt surface. The blue tones require a print considerably lighter than would be considered right; but the other solutions work best with a print of normal depth, or one if anything a little on the deep side. The results we have obtained are commendably free from stain, being quite clear in the high-lights. As an additional aid to the retention of this brilliance, and for the sake of permanency also, the makers advise varnishing the prints with Zapon varnish, a small phial of which accompanies each box of the solutions. The varnish is applied simply by placing a little of it on the dried print, and, with a small pad of cotton, rubbing it quickly and evenly over the surface, which is then rubbed dry with a pad of clean cotton wool. The prints should be mounted with the precaution to use a paste of little penetrative power, and should not be soaked before applying the paste. The price of the toners is 1s. per set, for either red or brown, blue or green tones. The Zapon varnish can also be obtained separately at 6d. per bottle.

RECEIVED.—Edwards' special transparency plates, as made by Mr. B. J. Edwards (B. J. Edwards and Co., Ealing Dean, London, W.). We shall report on these plates as soon as we have had an opportunity of using them.

## CATALOGUES AND TRADE NOTICES

MESSRS. JOHN DONE AND Co., New Barnet, send us the new issue of their price list of printing, enlarging, etc., a copy which they will send on application. Professional photographers should apply for the special professional list, which is despatched on receipt of trade card. From their thirty-three years' experience in the business Messrs. Done can offer very excellent work in all branches.

MESSRS. W. WATSON AND SONS notify us that they are now supplying the patent "Antinous" release for use on the "Spida" camera, and in the course of a fortnight will be able to supply also a release suitable for the "Verascope." The prices of these releases, which will be the usual 2 feet in length, will be 3s. and 4s. respectively.

MESSRS. GOLD, SMITH AND Co., of Salford, Manchester, have taken the whole of the premises at 44, Chapel Street, at which address they are holding an exhibition of accessories, backgrounds, etc., until January 20. Admission is by appointment—card obtainable on application.

CINEMATOGRAPH Fire.—Towards the close of a biographic entertainment at Merthyr last week, flames suddenly ascended from the operator's film, burning 150 yards of it. The front door was knocked off its hinges, and all the spectators, including 200 children, were got safely out of the building.

## MEETINGS OF SOCIETIES FOR NEXT WEEK (Continued.)

Jan.	Name of Society.	Subject.
18.....	Bolt Court School of Ph. Eng. ....	"The Use of Bichromate Salts in Photography." Mr. E. W. Foxlee.
18.....	Chelsea and District Photo. Soc. ....	"Holidays in Ireland." Messrs. Brown and Hurdman.
18.....	Southport Photographic Soc. ....	"A Visit to Grindelwald with a Photograph at Lucerne." Dr. H. L. Hawskley.
18.....	Sheffield Friends' Sch. Ph. Soc. ....	"Titles and Mounds." Mr. Zeph Carr.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held January 9, Major-General Waterhouse, I.A., President, in the chair. The Chairman announced that the Council had awarded the Progress Medal for the year 1906 to Dr. J. C. Janssen, of Paris, for his work in astronomical photography, for his researches in reversal, and for his other photographic work. An account of Dr. Janssen's work is published on another page. A paper by Mr. James C. Kingdon on "The Latent Image" was then read by the Secretary. The author said that physical theories of the latent image had lately been held in greater favour by scientific men. The molecule of the silver halide was thought to suffer a disturbance though not a disruption. Reference was made to the paper by Professor J. Joly before the Photographic Society of Ireland last year, and printed in the *BRITISH JOURNAL ALMANAC* for 1905. In this paper Professor Joly dwelt on the work of Dewar at low temperatures as bearing upon the question of the constitution of the latent image. "The conclusion," said the author, "was that the action of light on the silver halides lay in the borderland between chemical and physical phenomena, and before it could be completely solved more knowledge was necessary of the manner in which the energy of the ether was transferred to the molecule. The author proceeded to represent the constitution of the silver halide as that of two atoms held together not by a rigid bond but by an elastic force. Any movement which caused the silver atom to swing about its position tended towards the disruption of the molecule, but the disruption need not take place, and the molecule might remain in a condition in which it was susceptible to development. In the subsequent discussion one speaker thought that the paper had confused rather than explained the subject, and he dismissed as insufficient the method mentioned by the author for recognising traces of hypobromous acid—namely, that of smell. Mr. A. J. Bull thought that the analogies of the latent image with other admitted physical phenomena were so many and striking that the onus of proof was upon those who supported a chemical theory. He pointed out that the phenomena of reversal had their counterpart in the action of light on a plate of pure metallic silver, a case in which a purely chemical theory was not admissible. A welcome change from the tone of highly involved speculation which the discussion had assumed was provided by the Rev. F. C. Lambert, M.A., who propounded a number of problems such as:—(1) If the action of light is, as has been said, a case of synchronism of the ether waves with the period of vibration of the silver halide, and assuming as must be the case, that the silver halide has but one period of vibration, though the light falling upon it may be of various different periods, how is it that when the halide is exposed to the spectrum the action of light is not confined to one narrow line? (2) What reasons were there against the supposition that the action of light which produced the latent image was like in kind to that which produced visible effects on the same sensitive material? No answers were forthcoming to these and other questions. The Chairman, in a few remarks, laid stress on the fact that the action of light, in producing a latent image, was to be looked for not only in the case of silver bromide, or silver emulsions, but in the case of almost every substance under the sun. The examination of a large number of substances showed that the action of light was distinct in most unsuspected cases. A vote of thanks was passed to the author of the paper, who was present, but did not reply to any of the discussion.

ULSTER Amateur Photographic Society.—Mr. Thomas N. Murray, who for the past five years has worked with ceaseless energy in the interests of the Ulster Society, is resigning the secretaryship, but will, we understand, still continue his support of the society.

THE members of the Norwich Ladies' Camera Club have arranged to hold a three days' exhibition, in the Thatched Assembly Rooms, All Saints' Green, in Easter week, in aid of the Jenny Lind Infirmary.

**LEEDS CAMERA CLUB.**—The annual meeting of the above society was held last week, when the secretary's report and treasurer's balance-sheet were presented. The membership, it was stated, now stood at 215, which was a slight decrease during the year. Officers for the ensuing year were elected as follows:—President, Mr. John MacKenzie; secretary, Mr. A. Dawson Berry, Marshall Avenue, Cross-gates; vice-president, Mr. C. B. Howdill; treasurer, Mr. W. Yewdall; lanternist, Mr. R. Turley.

THE Manchester Amateur Photographic Society are holding a whist drive on Wednesday, January 24, 1906, for furthering the social element amongst the members.

**CROYDON CAMERA CLUB.**—Miscellaneous novelties, chiefly home-made, were in evidence on the 3rd inst. Mr. Edgar exhibited several ingenious and simple cameras of his own design for taking four or more photographs on a single plate with one lens. In one an eyepiece of a cheap telescope formed the objective. This was about one and a half-inch focal length, worked sharply at  $f/6$ , and the resulting negatives permitted enlargements up to eight diameters without noticeable loss of definition. Mr. Terry showed a "Geka" filter sandwiched between two pieces of plate glass, placed slightly in advance of the focal plane. He had found it satisfactory in use. An opinion was expressed that the filter would be improved by cementing it to the glasses with Canada balsam. Mr. Sellors, amongst other items, showed a convenient camera support, devised by himself, to be used when copying. By means of a parallel motion, vertical adjustments could be made with ease. Mr. Harpur exhibited a hand-camera which had accompanied him into the pellucid waters of a Dutch canal. A few repairs (to the camera) were necessary, and it now worked better than ever. From his account of the contretemps it would appear to be injudicious to take up a point of vantage with one foot on a steamer, the other on the jetty, and eyes glued to the finder, unless one is quite sure the steamboat is not on the eve of departure. Many really clever contrivances evolved by Mr. Harpur's fertile brain were also explained, including some thoroughly practical, albeit wonderful and fearful looking, sky-shades. Mr. Bawcomb showed some beautiful crystal formations by means of the polariscope, and the hon. secretary (Mr. H. M. Bennett) the latest T.P. blind shutter, neat in appearance and efficient in construction, together with a number of novelties of the Altrincham Rubber Co., which aroused much interest. A quiet and peacefully minded member, who had a large pneumatic plate-holder, unexpectedly and forcibly applied to a head somewhat "thin on top," indignantly denied the President's (Mr. W. H. Smith's) assertion that the appliance would also serve as a vacuum cap for encouraging the growth of hair. From the mode of application, he apprehended that the reverse might indeed be the case.

**RYDE PHOTOGRAPHIC SOCIETY.**—A meeting of the above Society was held on January 3, Mr. M. Maybrick, President, in the chair. The rules drafted by the Special Committee appointed for that purpose were with slight alterations approved. Mr. Harold Senier, Hanley House, Ryde, was elected honorary secretary and treasurer, and the following gentlemen were elected on the Committee:—Messrs. P. Chiverton, A. E. Jupe, N. Newbold, C. L. Priestly, J. Purnell, and A. H. Starnes. Messrs. H. B. Fowler, R. Fox, G. H. Harrison, and E. Urwick were elected vice-presidents of the Society. At the next meeting, the date of which will be shortly announced, Mr. A. H. Starnes, F.R.P.S., will deliver a lecture on the "Marvels of Photography," with special reference to photography in colours, illustrated with a number of unique and interesting lantern slides. A large number of the residents of Ryde interested in photography have already been enrolled as members of the society; any others desirous of joining may do so without entrance fee, if they will communicate with the hon. secretary prior to January 31.

**SOUTHAMPTON CAMERA CLUB.**—The annual general meeting of this Club was held on Monday evening, the 8th inst., at the Philharmonic Hall, when an enthusiastic meeting of the members was presided over by the President, Mr. W. Burrough Hill. The Committee's annual

report recorded the fact that the year had been a fairly successful one. The membership had reached a total of 161, while the work of the members had met with recognition all over the country. The exhibition held in December had only lacked public support to make it a complete success; in other respects it had been entirely satisfactory. The Committee had extended an invitation to the Photographic Convention of the United Kingdom, and that Convention would be held at Southampton in July next. The Club's indebtedness to the local and photographic press was cordially expressed, and the report, together with the statement of accounts showing a net increase on the year's working resulting in a balance on the credit side of £53 6s. 11d., was unanimously adopted. In the election of officers the great kindness of the President, Mr. W. Burrough Hill, to the Club, and the great amount of hard work done by the Hon. Secretary, Mr. S. G. Kimber, found free acknowledgment, and these gentlemen were re-elected, Mr. Kimber as Secretary, for the eleventh year in succession. The other re-elections were:—Vice-Presidents, A. Horsley Hinton, G. A. Vials, and G. Vivian; Hon. Treasurer, W. H. Trigg; Hon. Lanternist, G. Vivian; Hon. Reporter, F. G. Ryder; Committee, Messrs. Henley, Weaver, Baker, Kay (W. R.), Kay (C. D.), Miles, Daw, Cook; while Messrs. Essex and Copeland were elected in place of Messrs. Goatcher and Cooper. Extreme interest was shown in the further discussion of the Club's affairs; and, among other more formal matters, it was decided that the age limit of membership should be reduced from 16 years to 14; that the limit of radius for Club membership, which stood at fifteen miles, should be altogether removed; and that the Club membership fee should be seven and sixpence instead of five shillings, but that country members outside a six miles-radius should be admitted at five shillings. A hearty vote of thanks to the President concluded a prolonged and enthusiastic meeting.

## Commercial & Legal Intelligence.

**A CASE FOR P.P.A. ARBITRATION.**—At the Magistrates' Clerk's Office, at Woodbridge, last Monday, E. W. Jordan, of Woodbridge, a photographer, was charged with threatening Charles Edward Field, also a photographer, on Saturday night. It appears that the parties are in business in Woodbridge as photographers, and coming to some dispute the prisoner threatened to strangle the complainant, and knocked him about.—The prisoner was remanded in custody.

**FREE PORTRAIT SIDELIGHTS.**—The case of James McBurnie, summoned by his employer, Alfred Margand (Crown Art Co., Seven Sisters Road), for embezzling money, came before the Cambridge Police Court again on Saturday last. The defendant did not appear, and at the request of the prosecution the case was adjourned for a week. A lengthy account of the case appeared in our issue of December 22 last.

**ALLEGED THEFT.**—Before Mr. J. S. Hawker, at Stonehouse Police Court last week, Charles Christian, of no fixed abode, was charged with stealing four New Year cards, the property of John Easden, photographer, 21, Union Street. Complainant stated that on Wednesday afternoon accused came into his shop and asked to be shown some New Year cards, for one of which he paid eightpence. He left the shop, but returned shortly after, and was shown more cards. He asked the assistant to read the inscriptions on the cards, and whilst this was being done he was seen to put some cards in his pocket. When taxed with it he took no notice at first, but on complainant threatening to send for a constable he took the cards out of his pocket and threw them on the counter. Prisoner was remanded.

**ALLEGED CANVASSING FRAUD.**—Joshua William Humphreys, photographer, of Blandford, has been committed for trial by the Warminster magistrates on a charge of getting money from tradesmen by promising to print picture postcards and not doing so. Mr. Hibberd, of the firm of Hibberd Bros., of Heytesbury, declared that some of the Heytesbury cards that were delivered were marked Sutton Veny and those of that place Heytesbury. The police stated that there were two or three bushels of letters in defendant's house.

## COMPANIES REGISTERED.

**ATKINSON BROTHERS (LIVERPOOL), (1905), LIMITED.**—Registered December 23. Capital, £500 in £1 shares. Object, to carry on the business of photographers, photographic material merchants, publishers, chemists, etc. No initial public issue. The first directors are not named. Qualification, £10.

**LYTH ENGRAVING COMPANY, LIMITED.**—Registered December 27. Capital, £1,000 in £5 shares. Object, to acquire the business of an engraver and commercial photographer carried on by W. Lyth at Lancaster Buildings, Barton Square, Manchester, as Rhodes and Lyth. No initial public issue. The first directors (to number not less than two nor more than five) are W. Lyth, F. W. Richardson, and Hannah Lyth. Qualification, £25. Registered office, Lancaster Buildings, Barton Square, Manchester.

**BLAKE AND MACKENZIE, LIMITED.**—Registered December 22. Capital, £35,000 in £1 shares (30,000 preference). Object: To carry on the business of wholesale stationers, lithographers, stereotypers, photographic printers, engravers, etc. No initial public issue. The first directors and managers (to number not less than two nor more than five) are W. Blake, J. A. Bartholomew, C. Murray, and A. Grice. Qualification, £100. Registered office: Willmer Buildings, 10, School Lane, Liverpool.

**ANIMATED PHOTOGRAPH COMPANY, LIMITED.**—Registered December 30. Capital, £100,000 in £1 shares. Object: To develop and promote the use of the cinematograph in home circles, and to carry on the business of photographers, makers of and dealers in amateur and other cinematograph and photographic apparatus, films, pictures, lights, and accessories, caterers for public and private entertainments, etc. The signatories are:—Shares: V. C. Doubleday, 37, Wallbrook, E.C. 1; G. H. Cantrey, Hotel Great Central, N.W., 1; J. S. Chatterton, 41, Fitzroy Street, W., 1; E. A. Walker, 172, New Bond Street, W., 1; H. N. Phillips, 104, Inderwick Road, Stroud Green, N., 1; A. Lindsey, 7, Linton Villas, Crescent Road, Wood Green, N., 1; E. March, 59, Burton Crescent, W.C., 1. No initial public issue. The number of directors is to be not less than two nor more than six. The first are H. N. Phillips and V. C. Doubleday. Qualification, one share. Remuneration (except managing director), £50 per annum for the chairman, and £40 each for the others, with 5 per cent. of the profits available for distribution divisible.

## News and Notes.

**PHOTOGRAPHING ALIENS.**—The "Gazette" has announced that by a new regulation under the Penal Servitude Act, signed and declared urgent by the Home Secretary, any alien confined in a prison with a view to an expulsion order being made under the new Aliens Act may be photographed and measured in the same way as a criminal prisoner.

**RADIO-ACTIVITY.**—On January 4 Professor F. Soddy, M.A., delivered his presidential address to the members of the Röntgen Society. He took as his subject the present position of radio-activity, and in opening dealt mainly with modern views with regard to electricity and the material characteristics of the electron and its special application to high frequency. He performed an experiment illustrating the passage of radium emanation through a tube containing phosphorescent material into liquid air and its subsequent diffusion in the form of a gas. After dealing with the marvellous powers possessed by radium, he referred to the constancy and the value of gold, which might possibly be due to the action of disintegration of a similar character to that which occurred in the case of radium.

**FIRE in Aberdeen.**—Last week the Aberdeen fire brigade received a summons to the shop, 187, Rosemount Place, occupied by Mr. J. H. Rennie, photographer, where there was a small outbreak of fire. Before the brigade arrived, however, the fire, which was of a very trifling nature, was extinguished by a fireman from the sub-fire station at Nile End. The fire originated in the window of the

shop by a fairy lamp becoming overheated, and igniting a piece of cloth in the window.

**ULSTER Amateur Photographic Society.**—The twenty-first annual meeting of this society was held in the clubrooms, the Museum College Square North, on Monday last.—The President (Mr. David Elliott), in opening the meeting, said it was again his pleasant duty to present the gold medal kindly given by the Lord Mayor (Right Hon. Sir Daniel Dixon, Bart., P.C., O.L., M.P.), which was won by Mr. W. D. Elliott, the judge of the prints being Mr. Charles F. Inston, of Liverpool, who placed Mr. Thomas Bryans second.—The Hon. Secretary (Mr. Thomas N. Murray), in presenting the annual report, said the president and committee, in presenting their annual report, at the close of the twenty-first year of the society, have again the pleasure of announcing a satisfactory year's work. The members on the books at the beginning of the year numbered eighty-five. There were thirteen new members elected during the year; lapses, resignations, etc., nineteen, leaving a total membership at the end of the year of seventy-nine. The general attendance of members and friends has been good, and more interest taken in the work of the society. By the courtesy of the Right Hon. the Lord Mayor (Sir Daniel Dixon, Bart., P.C., D.L., M.P.), a handsome gold medal was presented for competition amongst members. Two silver medals have been presented for competition—one by a friend, the other by Mr. Charles Mitford Martin. In conclusion, the Hon. Secretary thanked the members, one and all, for the courtesy shown him during the last five years, as he thinks it time a new secretary was appointed. The Lord Mayor's gold medal, won by Mr. D. W. Elliott; award made by Mr. Charles F. Inston, of Liverpool. The hon. treasurer's report was satisfactory. For 1905 the following were appointed as office-bearers:—President, S. W. Allworthy, M.D.; committee, Messrs. J. Campbell Carson, Thomas N. Murray, J. B. Anderson, William McLean, Hugh Cochrane, jun.; D. J. Hogg, Thomas Bryans, J. Malcomson; hon. treasurer and librarian, Mr. C. Mitford Martin; hon. secretary, Mr. R. McGeahy; hon. lanternist, Mr. H. Cochrane, jun. Samples of the new paper, platinochrom, were distributed. This is an easily-worked paper, giving beautiful results. The lantern slides sent in for competition were kindly judged by Messrs. McLean, McGeahy, and Sumner. H. Cochrane and D. J. Hogg equal first, John Malcomson and T. Bryans equal second. The new president gave an interesting address on the art of photography.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### A WAGES QUESTION.

To the Editors

Gentlemen,—I am pleased to learn that "Comyn" is still flourishing, to the confusion of those correspondents who in 1900 asserted that he was overpaid because the current wage was only £3 3s. I did not take that view of the case then, and have since had ample confirmation that the more expert an assistant becomes the higher the wage he can command. We see that "Comyn" had taken advantage of every means of improvement, and thus had made it profitable for his employer to pay him double the ordinary wage of an ordinary commercial operator. The same is true of every photographic worker. Even within the last month I know of a firm offering £3 3s. per week for a carbon printer who is expert enough to do their work. Yet the current wage of carbon printers is much below this. I agree with "Comyn" in thinking that operators and printers do not take sufficient pains to reach the highest level, and, consequently, cannot take any opening which offers. An employer recently told me that the number of really high-class operators could be counted on the fingers of one hand. Can we wonder then that such men should be paid £5 to £6 per week, instead of the usual £1 15s. or £2. Some years of observation, I am loath to admit, have convinced me that ambition and a desire to rise in the world are by no means common amongst assistants. The majority remain content to receive £1 or £2 a week, and having this do not strive to improve themselves, and so attain to a better position and higher wages. The faculty of

"getting on" is mainly a middle-class virtue, and I see no means of improving the wages of employees in general except by inducing them to raise their standard of living.—Yours sincerely,  
January 6, 1906.

JOHN A. RANDALL.

To the Editors.

Gentlemen,—The letter from "Comyn" in your last issue on the above question is extremely interesting, and must surely have made the mouths of others besides mine water.

I am perfectly willing to take up other work, if I get the chance; for instance, I can work all the iron-printing processes, lantern-slide making, enlarging, reducing to within 100th of an inch, and make three-colour negatives, but I still remain an operator at £4 per week. This means posing the sitter, taking the negative, developing, and superintending the printing room. I am pretty busy the whole year through.

What I should like to know, and it is an important point, is how I am to find time to take lessons in collotype and kindred subjects and yet earn the money that is required to find my family in food and clothing, to say nothing about schooling and boots for the smaller members of the same. It is true that I generally manage to finish work about 6 p.m., and if it were possible for me to attend lectures at Bolt Court, etc., after that I should be very pleased, but up to the present I have not been able to see my way clear to reach these estimable polytechnics and get back to work again at 9 a.m. the next morning. No doubt there are others in the same predicament.

But supposing we do avail ourselves, how are we to obtain situations wherein we may get £6 6s. plus 19s., with a legitimate hope of an even extra 10s. per week? Am I justified in throwing up a certainty for an uncertainty, and spending money in between whiles?—Yours faithfully,  
Edinburgh.

JAS. CROMBIE.

#### ANOTHER CELLULOID FATALITY.

To the Editors.

Gentlemen,—With reference to your remarks on the above subject on page 3 of last week's issue, it surely would only be fair to draw attention to the enormous amount of celluloid that is used by cinematograph and other film makers, and yet we have not yet heard of a fatality or explosion or fire amongst them.

Again, last year, although there was a fire at one of the German film factories it did not start through celluloid, although it spread to this department. One striking feature about this fire was that although there was a very large stock of thin rollable celluloid, which was stored in metal cases, there was no explosion. Some of the metal cases were fused and perforated, and the celluloid simply burnt with a brilliant white flame. Obviously then, as you say, "but there is celluloid and celluloid."

Whilst it behoves all of us to be careful, there is no reason for us to be frightened.

A CINEMATOGRAF OPERATOR.

London, E.C.

**ROYAL KODAK PHOTOGRAPHS.**—Since announcing the exhibition of photographs by Her Majesty Queen Alexandra and other members of the Royal Family, now open at the Kodak Galleries, 115, Oxford Street, W., we have paid a visit to the collection, which numbers altogether 65 pictures. Twenty-four of the photographs, which throughout are bromide enlargements from small negatives, are by the Queen, and the other Royal personages who have graciously placed their negatives at the disposal of the Kodak Company are H.R.H. Princess Victoria, H.R.H. Prince Leopold of Battenberg, H.R.H. Prince Alexander of Battenberg, H.R.H. Princess Henry of Battenberg, S.A.R. le Duc d'Orleans, and H.R.H. Princess Victoria Eugenie of Battenberg. The collection includes a number of very interesting pictures, which are equally noteworthy as specimens of enlargements on the various brands of Kodak bromide paper. Visitors to the gallery, too, will have an opportunity of witnessing semi-private demonstrations of development and other operations as offered by Kodak, Ltd. At the time of our visit a lady was asking a demonstrator of infinite patience the question:—"Is pyro hypo?"

## Answers to Correspondents.

\*.\* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\*.\* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\*.\* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\*.\* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

#### PHOTOGRAPHS REGISTERED:—

L. Berry, 27, Chapel Street, Chorley, Lancashire. *Three Photographs of the Rt. Hon. Lord Balcarras, M.P.*

R. Burgess, 28, High Street, Congleton. *Two Photographs of Wm. Brocklehurst-Brocklehurst.*

Jakeman & Carver, High Town, Hereford. *Two Photographs of Mr. Percy A. Clive.*

W. A. Thomas, 45A, George Street, Hastings. *Photograph of Mr. and the Hon. Mrs. Freeman-Thomas. Photograph of Mr. Freeman-Thomas, M.P.*

**MATTEING P.O.P.**—Would you be so kind as to give me some method for taking the gloss off P.O.P. prints and glossy postcards. You will much oblige?—A Beginner.

Squeegee the prints to the finest ground glass, and strip off when dry in the way usual when glazing.

**RETOUCHING** (Reply to R. F.).—The prints are too heavy in tone, and hardly give you a fair chance of showing the touch, but from certain indications we should think your work of rather weak quality, especially if displayed on glossy paper and properly printed. Your finish is certainly open to great improvement. The lady in dark dress has had much of the character taken out of her face, although she would probably highly approve of the flattery—such is the vanity and bad taste of the average sitter. Study the modelling closer, and if sending again later on, kindly show your work on a glossy paper. State the time taken, and see that it is printed to a brighter and more pleasant tone than this batch.

**PRESS PHOTOGRAPHY.**—I shall feel much obliged if you would kindly inform me what to do to obtain an appointment on the staff of some paper as photographer. I have good experience and have made a special study of landscape work, and can write a good descriptive article.—M.

The only course is for you to address the various illustrated papers (see Willing's "Press Guide," 1s.), with specimens of your work, literary and photographic.

**A SUMMONS QUERY.**—I am much obliged for prompt reply to my query re summons. You leave me still in some doubt, however, as I am not sure whether your reply holds good only provided the order is given on a form upon which the announcement is made that "all accounts are payable in London," or whether this is a needless procedure. If some such statement is essential would it suffice that same appeared on the invoice sent on dispatch of goods?—F. PENNY.

It is not necessary to make the statement on accounts. Our last reply was worded without qualification.

**BOOK ON EMULSIONS.**—Will you let me know as to whether there is a book published which deals with various emulsions, as I want formulæ for P.O.P., bromide, gaslight, self-toning papers, and also for various plate processes. I have Abney's books, but was

wondering if there is a book dealing more fully, and specialising on emulsions with formulas, etc. There are a few in your Almanac, which are useful, but a more varied assortment would be of use to me.—C. L. K.

The only other book meeting your requirements is Dr. Eder's "Photographie Mitt Bron und Chlorsilber Gelatine" (in German). The publisher is W. Knapp, Halle a/S.

**AEROGRAPH WORK.**—I should be greatly obliged for your advice as to the best colours to use for working up bromide enlargements with the aerograph, especially the flesh tints. Can you recommend any work on the subject published at a moderate price?—G.

For the various shades and lines of flesh tints choose, viz., burnt carmine, madder carmine, or carmine alizarine, pink or rose madder, brown pink, madder brown; where the tints are needed, or for draperies, etc., mix with, or use singly (as necessary), yellow carmine, aurealin, ultramarine, cobalt blue, bistre, sepia, vandyke brown, olive green, sap green, and Payne's grey. The above are all fairly permanent colours, and transparent. Many others apparently suitable are not so, on account of their opacity, or fugitive nature. We know of no book published on the subject.

**R. MC.**—Use a good orthochromatic plate and a deep screen, and give a full exposure.

**COLLOTYPE.**—(1) Would you please let me know if the enclosed postcard of fireplace is a colotype? (2) If so, can you please tell me why so many colotype cards and views have a coarse grainy appearance as that of Pier Head, Liverpool (also enclosed); Is it anything to do with original negative?—C. WHITE.

(1) Yes. (2) The original must be suitable, and the one of the Pier Head is evidently very bad. You can get much better collotypes than these in this country.

**COLLOTYPE.**—I would like to get the addresses of several Continental colotype and colour printers. I suppose my best plan would be to get hold of a few Continental trade papers, but I don't know where to get them. If you can enlighten me in any way I shall be greatly obliged.—LEEDS.

Probably the German printing journals will contain some addresses. You will see the announcements of several good British colotype printers in our advertisement pages.

**ANXIOUS TO LEARN.**—Write to Mr. Jonathan Fallowfield, 146, Charing Cross Road, W.C., for his catalogue and instruction book.

**PLOUGHMAN AND OTHERS.**—In our next.

**F. GRIFFITHS.**—1. Mawson and Swan, Newcastle-on-Tyne, as makers of collodion; A. and M. Zimmermann for pyroxyline (cellodine). 2. "Wet Collodion," by Chas. W. Gamble, Is.

**PULLIGNY LENSES.**—Can you tell me how and where I can obtain "anachromatic" lenses such as those used by C. Puyo (calculated, I believe, by Pulligny) and mentioned in your "Almanac" on p. 732.

From H. Calmels, 150, Boulevard de Montparnasse, Paris.

**CAPITAL.**—We think your friends ask too much and you yourself offer too little; 10 per cent. is nearer the mark in putting out capital in such cases where the security is not great.

**INTENSIFICATION.**—1. Is potash ferrocyanide (or red prussiate of potash) a poison, and which is a fatal dose? To what extent is it dangerous for wounds on the hands, and what is the antidote? 2. Do you consider negatives or transparencies on gelatino-bromide or chloride intensified by bleaching with potash ferrocyanide, and redeveloped by amidol and not refixed, as being permanent? 3. When a negative on gelatino-bromide plate has been reduced by ammonia persulphate, what are the means of reinforcing the image? I make this latter query, as mercury bichloride is no longer suitable for a negative having passed through the ammonia persulphate baths.—XERO.

1. It is not a violent poison, and we have never found any ill-effects in handling it. Its danger lies in the fact that mixed with an acid, the highly poisonous prussic or hydrocyanic is formed. 2. We should prefer to give a momentary fixing, but we do not think the permanency will be appreciably impaired by its omission. 3. We cannot say. The action of intensifiers on plates reduced with persulphate is frequently

irregular. We should recommend you to try one of the silver intensifiers given on p. 957 of the "Almanac."

**LIFE-STUDY POSTCARDS.**—Last summer I sold a good many of the life-study postcards. They were exceedingly good gaslight or bromide prints. Can you tell me of any other firm or firms that issue similar photographic cards, as I should like a greater variety of the finest photographic studies, as I find they are greatly appreciated by the better-class customers?—OTHELLO.

We do not know of similar series. You could, no doubt, hear of such through a small advertisement in the "Journal," but you will not find anyone with such a large variety.

**OTHELLO.**—Probably you have not ascertained the working aperture quite accurately. A convenient method of doing so is as follows: Focus the camera on an infinitely distant object, and replace the focussing screen by a piece of cardboard with a pin-hole in the centre. Bring into the dark-room, and place a lighted candle behind the hole. A disc will be formed on the front surface of the lens, which disc is the true diameter of the working aperture. Dividing the focus of the lens by the diameter of this disc will give you the true number. A convenient way of obtaining the disc is to place a circle of bromide paper in the lens cap, and use an inch or two of magnesium ribbon instead of a candle as the light. The bromide paper is then developed.

FROM the report just issued we see that the sales of the Service Photographic Society during 1905 were nearly double those of the previous twelve months. During the year additional premises have been obtained facing directly on High Holborn.

THE South London Photographic Society will hold its 17th annual exhibition in the Camberwell Baths from March 5 to 10. Apparatus, which is always a feature of the exhibition, should be in evidence at the show, as we see that a single article can be shown on a general stand at the price of 1s. 6d. per square foot. Trade enlargers can also be accommodated with screens for the display of their work. Prices of these and other offers are contained in a special circular, now obtainable from Mr. Edward Pudy, 260, Southampton Street, Camberwell, S.E.

A CORRESPONDENT writes: "I should esteem it a favour if you could give me the address of the maker of 'Hall's pine gum' in your next issue of the B.J." [We cannot say. Perhaps the vendor will communicate with the querist through ourselves.]

A CORRECTION.—In our notice last week of Messrs. Epstein's new 20 by 16 frames we gave the price of 45s. per dozen as retail; it should have been wholesale.

"WILSON'S Photographic Magazine," our American contemporary which in the States looks after the interests of professional photographers, is losing from its editorial chair Mr. W. I. Scandlin, who for some year or two past has been responsible for its production. Mr. Scandlin's place is being taken by Mr. Tom Tennant, a brother of John A. Tennant, of "The Photo-Miniature."

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

An exhibition of colour-photography opens to the public to-day at the offices of the BRITISH JOURNAL OF PHOTOGRAPHY.

The pressure to which the silver salt is subjected in the film of emulsion is one factor in theories of the latent image which appears to be largely neglected by writers on the subject. (P. 42.)

Proposed alterations in the copyright law have been drafted by the Artistic Copyright Society. An examination of the Bill shows it to be so loosely worded that it must inevitably break down in practical legislation. (P. 44.)

Ultra-violet light as a means of obtaining increased resolving power in photo-micrography is attracting a good deal of interest amongst microscopists. (P. 45.)

Mr. R. J. Wallace has published some further tests of orthochromatic plates, charted from measurements of negatives exposed in accordance with the method printed in the B.J. for October 27 last. (P. 50.)

Relief effects in photographs by a combination of positives and negatives are among the patents of the week. (P. 52.)

A duplex method of cinematograph has been patented, one projection system being covered whilst another is in action. (P. 53.)

The third annual exhibition of the Scottish Salon is now being held in Dundee. A full notice of the professional work appears on p. 53.

A correspondent contributes an account of his methods of preparing lantern slides for the announcement of election results, as a postscript to his suggestion that the photographer should make a bid for business of this kind at a time when political agitation is robbing him of his ordinary custom. (P. 57.)

## EX CATHEDRA.

**An Exhibition of Colour Photography.** The collection of examples of colour photography representative of the present practice on glass and paper, to which we alluded last week, is to-day opened to the public at these offices at 24, Wellington Street, Strand, and will remain open until March 3. The exhibition, to which admission is free upon presentation of card, may be visited between the hours of 10.30 and 4.30—on Saturdays 10.30 to 12.30—and it is hoped that many ladies and gentlemen will be glad to take the opportunity of inspecting side by side the work of a number of well-known exponents of three-colour or other processes. A catalogue has been prepared in which brief technical particulars of the exhibits are printed, and while a copy will be presented to every visitor, intimation is hereby made that applications by post for a copy cannot be entertained.

## The Binocular Microscope and Stereoscopic Effect.

The question whether a true stereoscopic effect is obtained in the binocular microscope came up at a well-known photographic society a short time ago, and it appears that the discussion terminated, as such discussions generally do, without a decisive conclusion being arrived at. The real facts of the case appear to be as follows:—A binocular microscope may be so adjusted as to give a pseudoscopic, or a stereoscopic, effect; or so as to give what is practically a monocular effect. But, in the case of a binocular of the ordinary kind with only one objective, the stereoscopic effect produced is not that of a stereoscopic view of the object under the objective. It is simply a stereoscopic view of the three dimensional or "solid" real image formed by the objective, which image is invariably of a different form from that of the object. Take, for example, the case of a cubic object. The "solid" image formed by the objective is not a cube but a truncated pyramid, and the stereoscopic view obtained is one of the pyramidal image, not one of the cubic object. To obtain a true stereoscopic view of the actual object two objectives are necessary, as well as two eye-pieces, and the Greenough binocular appears to be the only instrument so fitted.

**Abbe's Papers on the Binocular Microscope.** Those who wish for further information on the subject (which is one of importance to all interested in stereoscopy) should refer to two papers by Professor

E. Abbe in the "Journal of the Royal Microscopical Society." One is entitled "The Conditions of Orthoscopic and Pseudoscopic Effect in the Binocular Microscope," and can be found in Vol. 1, 1881, p. 203; and the other is called "The Mode of Vision with Objectives of Wide Aperture," and is in the "Journal" for 1884, p. 20. In

the latter volume, at page 486, Dr. Carpenter opposes Abbe's statements, but there can be no doubt in the mind of anyone who studies the subject for himself as to the correctness of Abbe's views. Very unfortunately, Dr. Carpenter's erroneous theories with regard to the action of the binocular have survived, being put forward in considerable detail in the ninth edition of the "Encyclopædia Britannica," and it is quite possible that some of those who joined in the recent discussion have been misled by what may easily appear to be a most recent and authoritative explanation. Dr. Carpenter's paper in the "Journal of the R.M.S." is, however, one that should be carefully studied, for it contains some most valuable hypotheses with regard to what may be called the "Suggestion of Relief," which is a factor in the production of stereoscopic effect that is too often neglected.

#### The Latent Image.

In the recent discussion at the R.P.S. on Mr. J. C. Kingdon's paper on the Latent Image, (reported in our last issue) no mention was made of the characteristic curve of the plate, though it appears most probable that a study of this curve should afford evidence bearing on the subject of the discussion. For example, it is difficult to explain the concavity of the lower part of the curve, unless we assume that the silver salt has a certain power of self-recovery from a physical strain imposed upon it by the light. It is equally difficult to explain why the concave curve eventually becomes an approximately straight line unless we assume the gradual growth of a regularly progressive permanent effect not liable to self-recovery, which effect is, perhaps, more likely to be due to a chemical than to a simply physical change. As regards the upper part of the curve, the change from a straight line to a convex curve must be due simply to reversal (provided the film is of sufficient thickness to absorb and use up all the light that it receives), and while such reversal effects may in general be either of a physical or chemical nature, it seems natural to assume that they are most likely to be of the latter nature when conditions favourable to chemical change exist. In the case of the gelatine plate the presence of a bromide absorbent is undoubtedly such a condition.

#### Physico-Chemical Theories.

The true explanation of the latent image will probably recognise the existence of both physical and chemical changes, the former being perhaps solely effective in the lowest tones, while both occur in the intermediate tones. Chemical change alone may, perhaps, be responsible for the effects produced by extreme over-exposure. Dr. Eder's experiments, recorded in our issues of December 1 and 8, 1905, must distinctly suggest that different effects are produced in the low and high tones, even though the author himself seems to favour the idea of chemical change throughout. Those who favour the physical theory alone, and also those who pin their faith to a purely chemical theory, invariably seem to lose sight of the facts that chemical change must be preceded by a physical change, and that physical changes will speedily become chemical under favourable conditions. Those, also, who endeavour to either prove or disprove the existence of chemical change by the evidence afforded by partially analogous experiments seem apt to forget that the product found in the photographic film is formed under peculiar conditions that do not prevail in experiments on simple films or masses of silver bromide, one of these peculiar conditions being the enormous pressure to which the silver salt must be subjected in the dried gelatine film. It may be that the chemical product of the light action is one that cannot

exist excepting under these peculiar conditions, in which case it is hopeless to attempt to produce it otherwise.

#### The Celluloid Fatality.

In our issue of the 5th inst. we gave a report, as it appeared in the newspapers, of a fatality in Southwark arising from the ignition and explosion of celluloid. We then said that as an inquest would have to be held, and as there were eye-witnesses to the accident, we should learn how it really happened, whether from ignition or spontaneous combustion (a charge sometimes made against this material), and whether there was an actual explosion, as alleged. At the inquest, held one day last week, the evidence showed that, although the place was lighted by electric lights, the man who was killed was using a candle at the time. That, of course, dispels the idea of spontaneous combustion. It appears that the deceased was engaged in stacking sheets of celluloid in racks, and it was said there were 150 rolls of it in the basement of the premises where the mishap occurred, as well as 50lb. weight of celluloid umbrella rings. In his evidence, Colonel Fox, chief of the London Salvage Corps, said he had examined the premises, and considered it iniquitous that celluloid should have been stored in such a place, and it was criminal to take a light near it. This witness also said that celluloid was being used for many purposes, and he had lately noticed that it was employed for ladies' boot heels. What would happen if a lady wearing such heels were to put her feet in the fender or step upon a match he could not think. A large proportion of the mishaps with this material arise from those who employ it not knowing its dangerous character. Few ladies, we imagine, who wear imitation tortoiseshell combs in their hair are aware of the highly inflammable nature of the material of which they are made, or they would not purchase them. Some time ago we were in the warehouse of a firm of shipping agents when a large quantity of sheet celluloid was being packed for export. Gas was burning close to where the packing was being done, and neither the men who were handling it nor their employers had any idea of its dangerous character.

#### Use of the Royal Arms.

In last week's JOURNAL was published the list of photographers who are entitled to use the Royal Arms in their businesses. It is illegal for anyone whose name is not on the list to use the Royal Arms on their mounts, letter paper, show cases, or anything else. If anyone does so he renders himself liable to a fine of twenty pounds. We know that some persons are under the impression that if they have supplied photographs, or any article, to members of the Royal Family, or the King himself even, they are at liberty to put up the Royal Arms, and have them on their stationery, etc. This is entirely a mistake. To use them they must possess the Royal Warrant of Appointment, or they will render themselves liable to the above fine. Not only is it illegal to use the Royal Arms without the warrant to do so, but it is equally illegal to use any colourable imitation of them. While on this subject, we may mention that it is illegal to call a thing patent, or, in the case of trade marks or designs, registered, if no patent has been granted or registration effected. The fine for this is five pounds. Even if a provisional protection has been granted it is illegal to apply the term patent to it, and anyone who does so subjects himself to a five pounds fine.

#### The Evil of Low Prices.

A letter from a correspondent on another page states the case against the "free" or "invitation" sitting in terms which we can entirely endorse. The policy of allowing the public to think that

a photograph is a thing which can be made for nothing is one so far-reaching in its evil effects that no effort should be spared to resist its encroachments. We may be told that a free sitting is not a free sitting after all, and of course everybody knows that the customer has got to pay for his invitation some time or other. In which case we ask: Is it worth while to go this roundabout way of acquiring business at the risk of cheapening photography of all kinds in so doing? The bane of professional business at the present time is the notion of cheapness which the public has had drummed into it by the price-cutters and those who, under the guise of compliment, create the impression that it is worth while doing photography for nothing on the chance of possible orders. The public does not discriminate between good and bad or between special photographic work which is costly to do and that which can, in fact, be turned out at a low price. Thus it is that we get cases such as one before us, in which a well-to-do customer who had had some oil paintings copied cavils at a charge of 10s. per negative and print, and bases his idea of a fair price on the cut rate of three cabinets at a cheap studio, and on the fact that some photographers will take a portrait gratuitously. The free sitting has a good deal to answer for in the present depreciation of photographers' prices.

\* \* \*

**The Sale of a Formula.** A case which came before a county-court in the Midlands last week should be noted for its application in cases which are not uncommon in the photographic trade. A firm of enamellers purchased a formula from a chemist whom they were to pay £126. About one-fifth of this sum was disbursed at the time of purchase, and the chemist was now claiming the balance still owing to him. The defendant stated that he had embarked in the business on the advice of the plaintiff, who had estimated the works cost at £300. The cost, however, had proved to be nearly £3,000, and as the defendant had been unable to make anything of the formula, he had called in an enameller who employed his own prescriptions. He was bound by his agreement with the plaintiff not to show the formulæ to anyone, or obtain an opinion of them. The jury, however, found a verdict for the plaintiff, and the case may thus serve as an object lesson to persons who may have photographic formulæ offered to them to satisfy themselves (1) that the formulæ will do what is claimed for them, and (2) that they are actually information which is not public property. The first may be done by employing an expert to report on preparations made by the vendor under test conditions, and the second by insisting that the formulæ be submitted in confidence to someone well acquainted with the literature and practice of the process and above suspicion of making use of the trust reposed in him. These are conditions which we should recommend to those entering into negotiations with unknown parties. In several instances which have come under our notice the payments of experts' fees at a preliminary stage would have saved the purchaser much disappointment and monetary loss.

\* \* \*

**An International Exhibition of Photography.** As we intimated in a brief paragraph a week or two ago, an international exhibition of photography is to be held in Paris this summer in the Grand Palais of the Champs Elysées. An influential committee of patronage has been formed in France, including representatives of many of the important scientific and educational bodies, whilst the whole of the arrangements are under the direction of M. L. Gastine, the editor of our con-

temporary, "La Photographie Française." The scheme of the exhibition is a most ambitious one, and we can extend to M. Gastine in advance all our sympathy in the enormous task he has set himself. Meanwhile we may accede to M. Gastine's wish in making it known that it is the desire of the executive to preserve a strict impartiality in the organisation of the exhibition and to give to it a broad international character. It is pointed out that as Paris during the months of July and August, when the exhibition will be open, is the rendezvous of tourists from every part of the globe, the occasion is peculiarly favourable to showing all nationalities the latest advances in technical, artistic, scientific, and industrial photography.

\* \* \*

**A New Terror in London Streets.** Considerable alarm was occasioned on Friday night, last week, by an explosion which shattered some of the windows of Messrs. Swan and Edgar's establishment in Piccadilly Circus. It appears that some photographers were employed by the "Daily Mirror" to obtain a flash-light photograph of the Circus by night, and the powder exploded with a loud report which was heard even so far away as St. James's Park. In its issue of Thursday, following, which contains an illustration of the Circus, the "Daily Mirror" says that the reports in the newspapers were greatly exaggerated, and adds that the accident arose in this way:—"The damp, however, had affected the flash-light preparation of gun-cotton and magnesium, with the result that when it was ignited an exceptionally powerful explosion occurred." Although the reports in the newspapers may have been exaggerated, the fact remains that there was a very loud report, one or more windows were smashed, and a portion of the balustrade was dislodged and fell, though, fortunately, no one was injured. One thing is certain, and that is that considerable alarm was suddenly created—and to what good? Even without any very loud report the brilliant flash of magnesium on gun-cotton is sufficient to frighten spirited or nervous horses and may lead to very serious street accidents. Our contemporary claims that the photograph obtained is "undoubtedly the finest and clearest flash-light ever taken in the rain." Possibly it may be, but the reproduction of it, as it appears in the paper, does not say much for it: the greater portion of it shows as a negative instead of a positive. But apart from the merits of such pictures, should they be attempted, seeing the risk of street accidents they may entail? A startled horse may take fright and cause serious damage and, possibly, loss of life in a crowded thoroughfare. The L.C.C. have put a check upon flash-lights used for advertising purposes, and it may perhaps do something in the matter of flash-light photography in the streets, if a repetition of such serious incidents takes place.

\* \* \*

#### **Fireproof Screens for Arc Lights.**

One of the problems the photographer has to solve in the use of artificial light for portraiture is the danger of fire. Quite recently two cases have come under our notice which clearly indicate the risk. In the first instance, some silk near an arc portrait lamp became ignited by a piece of incandescent carbon, with the result that the lamp itself was considerably damaged. In the second case, a piece of glowing carbon fell upon a tracing linen diffuser, and lay there for nearly a minute before it could be removed. The tracing linen became scorched, and ultimately commenced to smoulder, but never burst into flame. In all probability a considerable quantity of gelatine is employed to render the linen translucent, and this is not an inflammable substance. Silk

and muslin near to a powerful lamp necessarily become in time "as dry as tinder," and will ignite from a spark almost. It is well to know that while second to nothing as a diffusing medium, ordinary tracing linen is perhaps the safest material that can be employed. There are a variety of asbestos cloths which may be used where the heat is great above or at the side of lamps, but these are not, of course, translucent. If fabrics are in proximity they may be soaked in a solution of alum or tungstate of soda and dried, when they become practically non-inflammable. The great practical utility of the electric arc lamp and its increasing use in portraiture render it well to avoid any prejudice which might be engendered were one or two serious accidents by fire to take place. The enclosed type of arc lamp is no doubt safer than the open arc, as it is almost impossible for a broken piece of carbon to fall out of the lamp.

\* \* \*

**The Word "Aerograph."** When Mr. Burdick lectured at the Society of Arts a few weeks ago one member of the audience asked for the etymology of the word applied to his ingenious instrument. It appeared that in America aerography is wireless telegraphy, a solecism against which Sir Henry Trueman Wood protested with some heat. Of course Signor Marconi's invention has nothing to do with the air, and is not drawing in any sense. We see that the "Globe," which is usually punctilious in matters of etymology, makes use of the word in the American sense, and nobody seems to have informed it that "aerograph" was certainly coined by Mr. Burdick at the time he invented his instrument for drawing with an air-blast some ten years ago.

#### PROPOSED ALTERATIONS IN THE COPYRIGHT LAW.

DURING the long period when the Committee of the Artistic Copyright Society were engaged in struggling with the perplexities of the law of copyright a report was issued by the Society appealing for patience on the ground of the magnitude of the task. We were told, of labours protracted into the hours of night, and other proofs of energy and perseverance. Considering the terrific nature of the effort, the result, the Bill which we print in full on pp. 47-49, bears singularly little evidence of careful consideration. In its intentions, the Bill, so far as photography is concerned, is an elaborate provision for making the conditions of copyright so difficult to comply with that, in the vast majority of cases, if the Bill were to become law, the natural owner of copyright in a photograph would inadvertently lose his rights. If the change were for the benefit of the community, or because photographers were unduly favoured, it could be borne philosophically, but it is not so. Scarcely an attempt has been made to disguise the object to be attained. That the illustrated press, and others commercially using photographs in a similar way, may obtain them without payment is the object. In fact, to enrich one class by legalising the plunder of another class.

It is perhaps fortunate that the Bill is as badly conceived and drafted as it is. The fact will at least cause it to receive careful reconsideration before any attempt to make it law, and during the reconsideration it will perhaps dawn upon some of those who have the matter to attend to, and who represent the painters' class, including black and white draughtsmen and the like, that in betraying the photographer they have unsuspectingly betrayed their own class; and any attempt to rectify the effect of this want of foresight must inevitably be in the nature of a more just recognition of the rights of photographers.

The Bill as it stands bristles with inconsistencies and ambiguities. The difficulty of drafting a Bill dealing with such a complex matter so that extraordinary occurrences may be provided for must, of course, be acknowledged and recognition accorded to the inevitableness of human fallibility overlooking minute details; but, allowing for reasonable lapses, the Bill should be able to bear the application of cases of every-day experience without breaking down or leading to ambiguities only to be cleared up by a judge's decision. Such a proviso as "Every assignment of copyright . . . other than . . . by testamentary disposition . . . shall be in writing" never ought to have been written at all, much less printed. In the two subsections which define the rights of the proprietor of copyright (Section 2, a and b) everything is included in (b) that is included in (a) that is of the slightest consequence, and (a) is merely unnecessary verbiage. Under Section 14 to forge the signature of a painter on a painting is forgery and punishable, as is the forgery of a signature on a document, but for similarly forging the signature of an engraver on an engraving from a picture or of a photographer on a photograph there is no remedy. It is not an offence under the Bill. The word "proprietor" is not used once in the Bill in such a way that a question could be raised as to its meaning, yet there is a clause professing to constitute a definition. It is a definition that does not define, and, as a matter of fact, literally, it allows under some circumstances for the contention that someone who has parted with the ownership of the copyright is the proprietor; but the clause is a particularly interesting one, apart from being an example of what to avoid in drafting a Bill, in supplementing evidence afforded elsewhere that the construction of the Bill was based on a misconception, and that the blunder originally made has never been discovered or rectified.

The Act of 1862 does not presuppose that the author must be the original proprietor of copyright in his work. It provides that he may be, but there is a qualification definitely stated under which he is not. In the case of his executing the work for a valuable consideration he does not retain the copyright. Copyright is not formally defined. In constructing the Bill under discussion the original proprietorship of the copyright in the author has been assumed. It is definitely stated in Section 1, although in Section 5 a condition is stated in which the author is not the original proprietor, and in Section 6 a provision is made under which he may not be the original proprietor. This discrepancy would be of little consequence if its only effect were to provide food for academical discussion, but it is a much more serious matter. The implication that authorship and copyright have necessarily some connection leads to some very curious results. The word "author," which has one meaning only, the creator of the work, in the Act of 1862, is used in the Bill in at least three senses:—In its ordinary sense, as the creator of the work; as the possessor of an abstract right, not alienated by parting with the copyright and transmittable to his successors; and as the owner of the copyright, whether he actually be the proprietor thereof or not. It is in the last connection that the most serious situations arise, and the extraordinary confusion that has been created in the attempt to depart from the simple method in the Act now in force of treating all classes of work alike will be equally exemplified in the same illustrations.

Section 22 provides that, before sale, copies of a work must be marked. In the case of the reproduction of an original work of fine art which has copyright under this Act with the author's name and the words "author's copyright."

Let us assume an ordinary case, and attempt to apply the provision. A publisher buys a painting of its author, with copyright. He contracts with an engraver for a plate with copyright, the assignments of copyright in each case being duly made. Each print from the plate has to be marked with the author's name and the words "author's copyright." Which author?—the author of the painting or the author of the engraving? And why "author's copyright," when neither author owns the copyright? And, further, what would happen if the publisher absolutely ignored the provision and sent his prints out unmarked altogether? Nothing! The case is unprovided for.

Let us take another case of the Bill breaking down. The same conditions as before, except that the publisher omitted

to obtain an assignment of copyright from the engraver. According to the letter of the Bill, if the publisher issued any impressions of that plate he would be liable to the engraver for infringement of his copyright. Section 6 is a two-edged sword which cuts on both sides. Sub-section (b) of Section 22 is quite as loosely worded as sub-section (a). It runs thus: In the case of the reproduction of any other work (each copy shall be marked).

We must leave a further consideration of the provisions of the Bill as they most closely affect photographers until another issue, but we have said enough to show that the Bill contains enough contradictions to give rise to endless discussions, and to stamp it at once as impossible of adoption in its present form.

## PHOTO-MICROGRAPHY WITH ULTRA-VIOLET RAYS.

AN interesting development in photo-micrography has been attracting considerable attention in the scientific world. The feature of the innovation is the substitution of the invisible ultra-violet rays in place of the ordinary white or blue light for "illuminating" the object. It has long been known that the resolving power of microscopic objectives is limited by the numerical aperture of the lens and the wave lengths of the rays used for illumination. The theoretical limit of resolution for an objective of 1.30 N.A., the object being observed by ordinary white light with wave lengths of  $.560 \mu$  is about 117.750 lines to the inch; with blue light, and consequently lesser wave lengths ( $.480 \mu$ ) a lens of the same numerical aperture might theoretically resolve a test plate of 135.850 lines per inch.

In order to utilise the increased power of resolution arising from the use of light of short wave lengths, a special apparatus designed by A. Köhler has been constructed at the Zeiss optical works which brings into action ultra-violet light with wave lengths of about  $.280 \mu$ .

As these rays are invisible to the eye the photographic plate is a *sine qua non* for this apparatus, and consequently it is constructed solely for photographic purposes. The first idea that presents itself in connection with this method of procedure concerns the all important question of focussing. As the rays are invisible, ordinary methods are useless. The difficulty is surmounted by the use of screens made of uranium glass which possesses the property of rendering the ultra-violet rays fluorescent. The object is first carefully focussed by means of a special piece of apparatus termed by the constructors an artificial eye, fitted with a screen of uranium glass, the image being viewed on the uranium screen, the artificial eye is then removed and the camera brought into position.

As the illumination from ultra-violet light could not be sufficient to give a distinct image on a uranium-glass camera-screen, all the focussing must be done with the artificial eye, which is so arranged that when the image is focussed by its aid an image is also focussed at a distance of 30 cms., this 30 cms. representing the camera extension used. When the artificial eye is swung on one side the image is focussed on the glass screen when the camera is brought into position, the dry plate afterwards being merely placed in the camera and the exposure made.

The ultra-violet rays are obtained by means of an induction coil with cadmium or magnesium electrodes, the latter being perhaps the most convenient metal. The electrodes should be separated by a short spark gap of about one third of an inch, as a short broad spark is necessary for the best results. It would be an interesting experiment to try the effect of a modern enclosed arc lamp for the source of illumination. The lamp is

largely used by process firms at the present time and is extremely rich in ultra-violet rays, the arc lamp would certainly be more convenient for use than an induction coil, but it is a doubtful question if it would yield sufficient ultra-violet light for the purpose.

The light from the magnesium electrodes passes through a quartz prism which throws the spectrum beneath the stage of the microscope, the ultra-violet band is received on a totally reflecting quartz prism by which it is deflected into the quartz substage condenser, and thence on the object to be photographed. A few preliminary trials are required with a screen of uranium glass before the ultra-violet light can be manipulated with the best effect on the lens field.

A vertical camera fixed on a pillar so that it can be easily swung out of the way when not in use is a material assistance in the manipulations. With this form of camera immediately the image is focussed on the eyepiece screen the camera can be swung into position and the plate exposed.

At the December meeting of the Royal Microscopical Society a number of photo-micrographs taken by the aid of ultra-violet rays were exhibited and afforded ample evidence of the value of the method. The photographs represented a variety of subjects, including the inevitable diatoms. The photograph that gave perhaps the best demonstration of the advantage to be gained by the use of ultra-violet light was a photograph of the shell of the diatom *Amphipleura Pellucida*. The photograph not only exhibited the lines on the shell (which in this diatom are equal to about 95,000 to the inch), but the lines were clearly resolved into rows of dots or points. The writer had seen some years ago a photograph of *A. Pellucida* taken by an ordinary objective and white light, in which the rows of dots were visible, but as they were only faintly discernible and merely a small portion of the shell which was in most accurate focus gave evidence of anything but continuous lines, the ultra-violet photograph was superior in every respect.

Ordinary microscopic objectives made of various kinds of glass are useless for ultra-violet work, and a special series of objectives and oculars composed entirely of quartz have been constructed. The objectives are of course all high powers of 6, 2.5, and 1.7 m.m. respectively. The two latter are immersion lenses. The 1.7 m.m. objective has a numerical aperture of 1.25, which is equal to about 2.5 when compared with a lens employed with white light illumination. For the immersion objectives cedar oil, which is practically the only medium now used for immersion objectives, is supplanted by glycerine and water for the quartz lenses.

A feature of the new method is the improvement manifested in the photographs of preparations in which the tissues have not been differentiated by staining. With white light many histological specimens will give little or no detail except the

sections have been suitably stained, but with the ultra-violet light the structure is often demonstrated in photographs obtained from unstained tissue.

### A DESCRIPTION OF THE

Supplementing what is said by our contributor, we may quote from the current number of the "Revue des Sciences Photographique," where an account is given of Dr. Koehler's instrument.

Fused quartz not showing double refraction, is therefore valuable for the construction of microscopic lenses, and, thanks to Dr. von Rohr, Zeiss has constructed an objective of N.A. 1.25 to 1.30. These objectives are corrected for spherical aberration, so as to satisfy the sine condition of "ny'sin u = n'y'sin u" for wave length  $275\text{ }\mu\mu$ ; they give this cadmium spectral line absolutely sharp. The light used being thus absolutely monochromatic, any correction for chromatic aberration is quite unnecessary. These objectives are called "monochromats." and Zeiss has constructed them as dry objectives with a N.A. of 0.35 and immersion objectives of N.A. 0.85, equivalent to 1.70 and 1.25, equivalent to 2.5. The immersion liquid is a mixture of pure glycerine and distilled water. The eye-pieces are either Huyghen's or Ramsden's, made of rock crystal, and the magnification is from 5 to 20 times, and they can be used for subjective examination or photography. The condenser, which has a N.A. of 1.30, is a glycerine immersion system, formed of four rock crystal lenses, the two upper lenses of which may be either alternately or totally replaced by an apianatic combination, which thus enables one to alter the focus and the N.A. of the condenser.

As the eye cannot see light on a short wave length, it is necessary to use some medium or special optical arrangement for subjective observation. The best thing for this purpose is a "finder" devised by Koehler, which may be compared to an artificial hypermetropic eye, of about three dioptries, sensitive to the ultra-violet. The refractive media of this are composed of two quartz lenses, and its retina is a screen of uranium glass, mounted in contact with a prism. The fluorescent image which is formed on this screen is examined by means of a powerful eye-piece, provided with a diaphragm, which is permanently connected with the finder. This finder, placed behind the eye-piece in a slightly inclined position, enables one to see the whole of the fluorescent image.

The slides on which the specimens are mounted should be made of thin quartz, and the cover glasses must of course be of the same material.

J. I. Figg.

### KOEHLER APPARATUS.

The advantage of the prism cemented to the uranium glass requires explanation. Under the influence of the ultra-violet rays most objects become fluorescent, and certain parts of them then emit light, and the result is that an image of these parts is produced according to the law of direct image formation and not according to that of secondary image formation of illuminated microscopic objects as

studied by Abbe. In the latter case the image of the object is duplicated, and this upsets the fluorescent image, and by the use of the prism the two images are differentiated, and one intercepted by the diaphragm of the eye-piece. On the other hand for certain work it is advisable to utilise the whole of the fluorescence.

The study of the minute structure of objects by the aid of the microscope is obviously best effected by the aid of the photographic plate. The finder is then merely useful to find the focal plane, which is then replaced by the dark slide, and this plane is then about 30cm. tube length. The amplification given by the monochromats and the quartz eye-pieces varies from 200 to 3,600, according to the tube length and camera extension of 24 to 34cm.

The light used must be absolutely monochromatic, and that which answers to this condition is produced by the spark between two cadmium wires, of 2mm. diameter, actuated by a Leyden jar of 0.002 microfarads, charged by an induction coil of 12cm. spark. A special spectroscope

devised by Koehler is used to isolate the particular wave length used, namely,  $275\text{ }\mu\mu$  (No. 17, of Moscart). This spectroscope consists of a collimator which parallelises the rays, two quartz prisms and a quartz telescope, which gives at its focal plane an image ten times the size of the spark. A total reflection prism of rock crystal placed below the microscope transmits to the Abbe condenser the image of the spark formed by the collimator. The adjustable diaphragm plate of the condenser is provided with a screen of uranium glass, which is used to define the focal plane of the image of the spark projected by the condenser.

Koehler's Apparatus, showing the camera turned back for ocular inspection.

The new method of investigation by means of the ultra-violet rays of  $\lambda 275$  certainly presents many advantages; in the first place the resolving power is doubled. The opacity of certain parts of the tissues to the ultra-violet rays produces practically an optical differentiative similar to that produced by stains. Examinations by

$\lambda 275$  enables us either to affirm the results obtained by our usual visual methods of examination, or to check them or to find out new facts. Ultra-violet light renders fluorescent certain parts of the tissues, which then emitting a light of their own, thus makes it possible to use achromats or apochromats of lower N.A.—that is to say, of dry systems.

## A PROPOSED COPYRIGHT BILL.

We now give the full text of the Bill which has been drafted by the Artistic Copyright Society. The salient points of the Bill were printed in our issue of December 22 last, but for a proper consideration of the very complicated and involved wording of the provisions it is necessary for the complete text of the Bill to be before the reader. Our comments on certain important proposals in the Bill will be found on another page.

DRAFT—Subject to Revision.

### A BILL INTITLED AN ACT TO CONSOLIDATE AND AMEND THE LAW RELATING TO COPYRIGHT IN ARTISTIC WORKS.

Be it enacted by the King's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

#### PART I.

##### NATURE AND DURATION OF RIGHT.

1. The author, being a British subject, of any work of fine art, photograph or cast from nature, made after the passing of this Act in any country whatsoever, and the author, whether a British subject or not, of any work of fine art, photograph or cast from nature, made after the passing of this Act in any part of the British Dominions shall have throughout the British Dominions copyright as defined in this Act.

2. The copyright in any work the subject of this Act shall consist in the exclusive right of the author or other proprietor for time being to do or permit to be done, or cause to be done, any of the following acts, viz.:—

- (a) To make for sale, distribution, exhibition or hire any copy of such work as defined by this Act;
- (b) To sell, distribute, exhibit or let for hire, or offer, or keep for sale, distribution, exhibition or hire of any such copy;
- (c) To import into or export from any part of the British Dominions any such copy.
- (d) And all copies made or dealt with in infringement of the said exclusive right shall be unlawful copies within the meaning of this Act.

3. The copyright conferred by this Act shall endure for the following terms:—

- (a) In the case of an original work of fine art, for the life of the author and until the expiration of thirty years after the end of the year in which he died.
- (b) In the case of a work of fine art, made by one person from any work of fine art designed by another, of a cast from nature, and of a photograph, for a term commencing on the completion of such work, cast, or photograph, and continuing until the expiration of thirty years after the end of the year in which the same shall have been completed.

4. Every assignment of copyright under this Act, other than an assignment by operation or devolution of law or testamentary disposition, and every license respecting the same, shall be in writing signed by the assignor or licensor.

5. (1.) In case any work, the subject of copyright under this Act, shall be a portrait made on the request of any person, for pecuniary consideration, the copyright in such portrait shall, on payment of the consideration and in the absence of agreement in writing to the contrary, belong to such person. But this shall not extend to a work of sculpture intended for a place or building of a public nature.

(2.) For the purposes of this section any work shall be considered a portrait whose principal object is the likeness in any form of art of any specified person.

6. Except as in this Act provided, the right of first publication,

and the copyright in any work the subject of this Act shall remain in the author, whether such work be sold or disposed of by such author or not, unless the right to publish the work or the copyright therein be expressly assigned or disposed of in writing by him; or pass by operation, or devolution of law, or testamentary disposition.

7. In the case of an artist sending a sketch or drawing to an editor for publication, the act of sending this sketch or drawing, and its acceptance and payment therefor is to be taken as conveying the copyright from the artist to the proprietor of the publication.

8. (1.) If any work the subject of copyright under this Act forms part of any scene, the copying of such work, merely as forming part of such scene, shall not be deemed to be any infringement of the copyright in such work, unless the special purpose for which the scene is represented is the copying of such work.

(2.) Notwithstanding anything in this Act contained, sketches, studies, models and casts, used in executing any original work of fine art may, in the absence of agreement in writing to the contrary, be used or dealt with by the author of such work, without infringing the copyright in such work, provided that he does not thereby repeat or imitate the main design or any essential feature of the work

#### PART II.

##### INFRINGEMENTS AND REMEDIES.

9. If any person shall infringe the copyright in any work the subject of this Act, by doing, or causing to be done, any act the exclusive right to do or permit which is by this Act reserved to the proprietor of the copyright in such work, without the consent in writing of such proprietor, such person shall be liable to:—

- (a) An injunction to restrain such infringement.
- (b) Damages, or at the option of the party suing, an account of profits.
- (c) Penalties of an amount to be fixed by the jury hearing the case, or if there is no jury, by the judge, not exceeding ten pounds for each offence. Provided always that in the case of an infringement appearing in a newspaper, book or similar publication, or in an advertisement thereof, a penalty of a lump sum may be substituted.
- (d) An order for delivery up on oath for forfeiture or destruction of all unlawful copies.

10. (1.) Any person having in his possession or control any unlawful copies of any work the subject of this Act, shall, upon demand in writing served upon him by the proprietor of the copyright, or any other party aggrieved, make to such proprietor, or other party, within forty-eight hours after service of the demand, full discovery of the name and address of the person from whom he obtained the unlawful copies, the number thereof, and the date when they were obtained, and of all invoices, accounts, and other documents relating thereto; and in default of such discovery may be summoned before a Court of Summary Jurisdiction, and ordered under a penalty of ten pounds to give such discovery within a reasonable time to be appointed by the Court.

(2.) Any failure to give such discovery shall be deemed *prima facie* evidence, in any proceeding for penalties or otherwise under this Act, that the person so failing had reasonable ground to suspect that the copies so dealt with by him, were unlawful copies within the meaning of this Act.

11. Any Court of Summary Jurisdiction, on the application of the proprietor of the copyright in any work the subject of this Act, on being satisfied that there is reasonable ground to suspect that unlawful copies of any such work are to be found in any house, premises, or other place within its jurisdiction, shall grant a warrant to any constable to search for such suspected unlawful copies in such house,

premises, or other place, between sunrise and sunset, and to seize and bring before the Court any such suspected unlawful copies, and the Court on proof that such copies are unlawful copies within the meaning of this Act, shall order them to be destroyed or delivered up as forfeited to the proprietor of the copyright.

12. (1.) If any person in any street or highway or elsewhere than at a house or shop, shall hawk, carry about, sell, or offer for sale any copy suspected to be an unlawful copy of any work, the subject of this Act, every such suspected unlawful copy shall be summarily seized by any constable, without warrant, on the request in writing of the apparent owner of the copyright in such work and at his risk.

(2.) On seizure of any such copies, they shall be conveyed by the constable seizing them before a Court of Summary Jurisdiction, and the Court on proof that such copies are unlawful copies within the meaning of this Act, shall order them to be destroyed or delivered up as forfeited to the proprietor of the copyright.

(3.) An order for destruction under this and the preceding section may, if the Court think fit, be made *ex parte*, and, pending the making of an order, the copies seized shall be detained by the Court.

13. All unlawful copies of any work, the subject of copyright under this Act, imported into any part of the British Dominions, shall be detained and confiscated by the officers of His Majesty's Customs on receipt by them of a notice in writing, duly verified, from the apparent owner of the copyright in such work, declaring his title to and the period of duration of the copyright, together with a description, photograph, sketch, or copy of such work.

14. (1.) If any person fraudulently signs or otherwise affixes or causes to be signed or affixed upon any work of fine art, any name, initials, monogram, or distinctive mark so as to give reasonable ground for belief, contrary to the actual fact, that such work is an original work of fine art, executed by an author either then alive, or who died within thirty years preceding the acts complained of, such person shall be guilty of forgery and punishable as for the forgery of a signature on a document.

(2.) If any person commits any of the following offences:—

- (a) Fraudulently sells, distributes, exhibits, lets for hire, or offers or keeps for sale, distribution, exhibition, or hire, any work of fine art so falsely signed or marked as aforesaid or permits, or causes to be done any of the said acts.
- (b) Fraudulently sells, distributes, exhibits, lets for hire, or offers or keeps for sale, distribution, exhibition, or hire, any work or the copy of any work the subject of this Act, representing, contrary to the fact, that such work or copy was executed by, or from the work of, an author then alive, or who died within thirty years preceding the acts complained of, or causes to be done any of the said acts,

he shall be guilty of an indictable misdemeanour punishable by imprisonment for a term not exceeding two years, and he shall (without prejudice to any other remedy) be liable to a penalty not exceeding one hundred pounds, to be paid to the person aggrieved.

(3.) The provisions of Sections 10, 11, and 12 of this Act shall apply to such false or fraudulent works or copies in the same way as if they had been unlawful copies within the meaning of the Act.

15. (1.) When the author of any original work of fine art, the subject of copyright under this Act, shall have sold or otherwise parted with the possession of such work, no material alteration shall afterwards be made in such work by addition or otherwise except with the consent in writing of the author, unless the author's signature or mark be removed from the work.

(2.) Neither shall it be lawful during the continuance of the copyright (except with the consent in writing of the author) to sell, exhibit, let for hire, or offer for sale, exhibition, or hire any altered original work of fine art or copy thereof or altered copy of an original work of fine art as or for the unaltered work or copy thereof or copy of the unaltered work of such author.

(3.) Any person who shall knowingly commit or cause to be committed any infringement of the above provisions shall be liable to the like penalty as is by the last section provided for the issue of a false or fraudulent work or copy, such penalty to be payable to the author of the original work, without prejudice to any other remedies of such author, or any other person aggrieved.

16. (1.) In any action for infringement the person sued must deliver

with his defence or at any subsequent time which the Court may appoint, particulars of any objections on which he relies in support thereof; and, if one of the grounds of objection is want of originality or of title in the person suing, he must state the name and address of the person whom he alleges to be the true author of the work or proprietor of the copyright, and the title and date of any alleged previous work or publication.

(2.) On the trial of the action, in the absence of such objections, the title of the person suing shall be taken as admitted, and no evidence shall (except by special leave of Court) be admitted in proof of any alleged objection of which particulars have not been so delivered; but any particulars delivered may be from time to time amended on such conditions as to costs and otherwise as the Court shall think fit.

17. No person shall be excused from answering any question upon examination as a witness, or from making any discovery either in answer to interrogatories or of documents, on the ground that such answer or discovery may render him liable to the penalties imposed by this Act. Provided always that no answers or discovery which any person shall be compelled by this Act to make, shall be admissible in evidence against him in support of any criminal proceedings.

18. (1.) All penalties and fines which shall be incurred under this Act may be recovered, and all unlawful copies and other things which may be liable to forfeiture or destruction under this Act may be dealt with either by action against the party offending, or by proceedings before a Court of Summary Jurisdiction in that part of the British Dominions where the offender is found, or the act complained of has been committed, or where the unlawful copies or other things are.

(2.) All remedies conferred by this Act shall be cumulative, but the Court or jury shall have a discretion as to awarding penalties, in addition to damages, in any case where the defendant shall prove due compliance with any demand for discovery served on him as provided by Section 10 of this Act.

(3.) The costs of all proceedings under this Act in which an infringement shall be proved, shall, unless the Court shall otherwise direct, be taxed as between solicitor and client so as to give the person aggrieved a full indemnity for all his expenses.

(4.) All false, fraudulent or unlawful works, or copies to which any of the Sections 13, 14, or 15 apply, shall be liable to destruction, or may be ordered to be delivered up on oath as forfeited to the person aggrieved.

(5.) Where any works or copies become liable to seizure, forfeiture, destruction or confiscation under this Act, such liability shall extend to and include all plates, blocks, negatives, moulds, or other similar things from which any of such works or copies were or may be produced.

### PART III.

#### REGISTRATION AND MARKING.

(19.) (1.) There shall be kept at the Hall of the Stationers' Company by the officer appointed by the said Company for the purposes of the Copyright Act, 1842, a book entitled "The Register of Owners of Copyright in original works of Fine Art" wherein may be registered the proprietorship of the Copyright in any original work of Fine Art the subject of this Act, including such works first made in the United States of America by a citizen thereof, and any assignments thereof, and any assignment so entered shall be effectual in law without being subject to any stamp or duty, and shall be of the same force and effect as it had been made by deed.

(2.) Application for registration and the entries in the register made thereon shall be in the forms and contain the particulars set out in the First Schedule hereto, with such modifications as the Stationers' Company may from time to time prescribe.

(3.) There shall not be entered in any such register any notice of any trust, express, implied or constructive.

(4.) The said officer shall make and keep full indexes of all entries made under this Act, arranged alphabetically so as to show (a) the title or description of the work, (b) the name of the author, and (c) the name of the proprietor, with references to the place in the register where the full particulars of registration may be found.

(5.) The said officer shall have power, upon written application being made to him by any registered proprietor, and on his being

satisfied of the existence of any inaccuracy in the registration (without prejudice to any pending proceedings), to make any correction in the name, address or description of the author or publisher, or of such proprietor, or in any other matter as stated in the original application for registration.

20. The registration of a person as proprietor of the copyright in any original work of Fine Art shall be *prima facie* evidence of his ownership of the copyright.

21. Save as herein provided the several enactments contained in Sections 11, 12, 13 and 14 of the Copyright Act, 1842, shall apply to registration under this Act in the same manner as if such enactments were here repeated at length so far as the same are applicable, except that the fee for making any entry or giving any certificate shall be the sum of one shilling only.

22. (1.) Before delivery on sale, or for hire or exhibition of any copies of a work the subject of copyright under this Act, the persons publishing such copies shall cause every such copy to be marked as follows:—

(a) In the case of a reproduction of an original work of fine art which has copyright under this Act with the author's name and the words "Author's copyright,"

(b) In the case of a reproduction of any other work with the name of the proprietor of the copyright and the year of completion of the work, together with a notification that the said work is copyright. And if he fails to do so, no action shall be sustainable nor any penalty be recoverable by the proprietor in respect of any copies of such work made in good faith by other persons, unless such proprietor shows that he took proper steps to secure the marking of all copies issued by him.

(2.) Any person who shall falsely mark or cause to be falsely marked any copy of a work requiring to be marked under the previous sub-section shall be guilty of an indictable misdemeanour, and shall in addition be liable at the suit of any party aggrieved to a penalty not exceeding ten pounds for every such offence.

#### PART IV.

##### SUPPLEMENTARY PROVISIONS AND DEFINITIONS.

23. (1.) The copyright existing in any work of fine art, photograph, or cast from nature by virtue of any enactment in force immediately before the commencement of this Act, shall endure for the term limited by such enactment, or for the term fixed by this Act with respect to such works first made after the commencement of this Act, whichever is the longer.

(2.) The provisions as to registration or marking of copies of such existing works, and the remedies for infringement of copyright therein, and otherwise shall be the same as for works completed after the commencement of this Act.

(3.) The registration of any original work of Fine Art first made in the United States of America by a citizen thereof, if effected within twelve months after the first recording of the copyright in the said United States, shall confer the same rights on the proprietor as if the said work had been first made in the United Kingdom.

(4.) Nothing in this section shall diminish or prejudice any rights or interests subsisting at the commencement of this Act.

24. The Acts specified in the second Schedule to this Act are hereby repealed, provided that the copyright in any existing work registered in pursuance of any enactment hereby repealed shall be deemed to be registered in pursuance of this Act.

25. Subject to the modifications contained in Section 6 hereof nothing in this Act shall affect the right of any person at common law to prevent the publication of an unpublished work, and until publication the person entitled to the right of first publication shall have all the remedies for infringement given to proprietors of copyright by this Act.

26. A licensee shall have all the remedies for infringement possessed by a proprietor of copyright under this Act in so far as his interest shall extend but no further or otherwise.

27. Nothing in this Act shall confer copyright in any profane, libellous or indecent work.

28. An agent duly authorised in writing may do for an author or proprietor of copyright, any act required or authorised by this Act

to be done by him, and every act so done shall be as effectual for all purposes of this Act as if done personally by such author or proprietor.

29. In and for the purpose of this Act, unless the context otherwise requires,

(1.) "Work of fine art" shall mean and include every painting or drawing, sculpture, and engraving, as hereinafter defined, and any other like work of fine art, and shall include any design of an artistic nature applicable or applied to any article of manufacture whether so applicable or applied in respect of the pattern, or the shape or configuration, or the ornament thereof.

(2.) "Painting or drawing" means any painting or drawing in any medium or material, executed by hand and not by printing or any mechanical or chemical process.

(3.) "Sculpture" means any statue, sculpture, model, or cast (other than a cast from nature), carved or made in any material either in the round, in relief, or in intaglio by any process.

(4.) "Engraving" means any work executed by hand and not by photography, or any mechanical means, upon any material whence prints or impressions of such work may be taken or multiplied, immediately or mediately by any process, and includes any prints or proofs so taken.

(5.) "Original work of fine art" shall mean a work of fine art made by a person from or according to his own original design.

(6.) "Photograph" shall mean and include every work produced by any photographic process upon any material whence prints or copies of such work may be taken or multiplied definitely or indefinitely, and shall include any such work though developed or finished by hand, or by any mechanical means.

(7.) "Cast from nature" shall mean and include all moulds of natural objects or parts of such objects and all casts made from such moulds.

(8.) "Proprietor" shall mean and include the author of the work and his representatives, and any person acquiring from him or them the copyright in the work, and any person in whom the property in such copyright shall subsist, or on whom the same shall devolve, shall be considered the proprietor thereof.

(9.) "Author" shall in relation to a photograph mean the person who shall himself (not being an employe or assistant) have taken the original photographic negative or positive and prints or copies therefrom, or in the case of a person who employs another person to do the work and who gives pecuniary consideration for work done, such employer shall be considered the author of the work.

(10.) "Copy" shall, subject to the provisions of this Act, mean any representation or reproduction of a work, or any part thereof, or the design thereof, in the same or in any other form, and in any material and in any size; and shall include:—

(a) A reproduction of a work by using or applying it either in the pattern, or in the shape or configuration, or in the ornamentation of any article of manufacture.

(b) A reproduction of any other work of fine art or photograph by a sculpture, or of a sculpture by any other work of fine art or photograph; and

(c) A representation of any work by a living picture, or by any other means whereby the design of the work is reproduced.

30. All actions and other proceedings for any penalties under this Act shall be commenced within 12 calendar months after the discovery of the offence or shall be of no effect.

31. (1.) This Act may be cited as "The Artistic Copyright Act, 1906."

(2.) The expression "The Copyright Acts," wherever it occurs in the International Copyright Act, 1886, or any Order in Council to be construed as part thereof, shall be deemed to include this Act.

32. This Act shall come into operation on the First of January, One thousand nine hundred and seven.

The necessary Schedules to follow.

"TABLOID" Demonstrations.—Messrs. Burroughs, Wellcome, and Co., have fitted up a studio and demonstration room at their chief offices, Snow Hill Buildings, Holborn Viaduct, E.C., and are now prepared to give the attention of their staff to personal inquiries from those experiencing any difficulties in the use of "Tabloid" chemicals.

## A SECOND NOTE ON "ORTHOCHROMATIC" PLATES.

[The following note, which is sent to us by the author from the Yerkes Observatory, as a reprint from the "Astro-Physical Journal," continues the charting of tests obtained by the method described in the previous paper by Mr. Wallace, which appeared in our issue of October 27 last.—Eds., B. J. P.]

FIG. 1.

The "sensitiveness-curves" in Fig. 2 accompanying the present paper were plotted from negatives obtained under precisely similar conditions to those described in my "preliminary note" (B. J., October 27, 1905).

Light-Units  
300

FIG. 2.—Sensitiveness-Curves in Light-Units.

In considering the series recording the selective sensitiveness of the Cramer "Slow Isochromatic" plate, an interesting condition was observed, which, in brief, amounts to a reversal of curve according to whether "under" or "normal" exposure be considered.

In the record of this plate (Fig. 1), it will be noted that beginning with the 5 seconds exposure, up to and including that of 30 seconds, the maximum sensitiveness lies decidedly in the violet about  $\lambda$  3900-4100. With the 1 minute exposure, however, the yellow-green sensitiveness is slightly in excess of the former, and gains in density

FIG. 3.—Density-Curves Corresponding to Plates Plotted in Fig. 2

very rapidly with increasing exposure, until at 8 minutes it is far ahead, and has then reached the point of greatest allowable opacity. In the meantime, the blue-violet has but slightly increased.

The dye incorporated in the emulsion during the preparation of

the plate stains it with a heavy greenish-orange hue, which shows a definite absorption band in the yellow-green from  $\lambda$  5400-5800; while in the violet the absorption is very strongly marked, shading off gradually in the blue. The sensitiveness-curve, for normal ex-

posure is therefore resultant from a combination of emulsion and "light-filter."

The light which falls upon the surface of the film ("under-exposure") affects first the blue-violet—the region of maximum sensitiveness; but, as it penetrates (by lengthened exposure) farther into the film, the violet and blue light is more and more absorbed, while the yellow and green is transmitted with but slight loss.

It will be noticed that these curves, Fig. 2 (B. J., October 27, 1905), and Fig. 2 (herewith), have been plotted with "opacity in light-units." This differs from the method of Hurter and Driffield, who measure opacity, but plot density. The investigations of these workers have proven that in a theoretically perfect negative the quantities of silver reduced at different points are proportional to the logarithm of the light producing them; the deposit of silver (density) representing the amount of chemical work accomplished by the light. By plotting these spectrum negatives as "opacity in light-units" the curves serve as an indication of the relative exposure for pure colour. At the same time they should also be plotted as densities, for, the transparency of the light being reduced by the density, such a curve is the measure of the printing value (Figs. 3 and 4).

As a check upon the opacity estimation of these curves, it was thought advisable to adopt some method of "proving" them. A density-curve was therefore selected (Cramer "Instantaneous Isochromatic") which had been plotted from the opacity-curve already published, and which should be, theoretically, exactly the inverse of the original.

FIG. 4.—Density-Curves Corresponding to Plates Plotted in Fig. 2.

This was mounted upon a sheet of opaque paper and its area carefully cut out, then placed in a camera, and an image projected of a size comparable with the original negative. This last adjustment was readily effected by making pinholes through the paper mask at the positions of the Fraunhofer lines (abscissae) and focusing the bright images to size. By means of a plate swinging vertically the image of the curve was caused to impress itself with varying density, the pinholes being distinctly shown as slightly darker lines crossing the negative of the artificial spectrum thus obtained.

This negative was found to be closely comparable with the original spectrum negative, when due allowance was made for the effect of the Fraunhofer lines in the latter. Comparison prints are shown in Fig. 5, in which one-half of the height of the artificial spectrum has had the lines drawn in by hand, while the remaining half is untouched.

The result of the speed tests for the plates represented in this second note is (while still taking the Cramer "Instantaneous Isochromatic" as 1.0), as follows:—Standard "orthochromatic" = 0.75; Cramer "slow isochromatic" = 9.00; Warwick "Rainbow" (slow) = 2.00; Wellington "Iso speedy" = 1.17. Thus it would appear that the "slow isochromatic" has a speed of one-ninth that of the "instantaneous isochromatic."

ROBERT JAMES WALLACE.

MR. WOLFGANG ARNDT, the teacher of retouching notifies us that he has removed to 8, Carlton Vale, Maida Vale, N.W.

## THE SCOTTISH PHOTOGRAPHIC FEDERATION.

### ANNUAL MEETING.

Last Saturday the annual general meeting of the Scottish Photographic Federation was held in Dundee. Over thirty delegates and a goodly number of associates were present, presided over by Mr. G. D. Macdougald, F.I.C., President. The Secretary (Mr. John B. MacLachlan) presented the annual report which we print below.

The financial statement of the Treasurer (Mr. Arch. Campbell) showed a balance of £33 7s. 6d., compared with £29 3s. 3½d. in 1904. Both reports were unanimously approved.

It was agreed that in future the Council appoint the Board of Selection for the annual salon. Mr. R. Milne, Secretary of the Paisley Philosophical Institute (Photographic Section), submitted an invitation from that body to hold the 1907 Salon at Paisley. The invitation was unanimously accepted, and the inviters heartily thanked.

The reward of hard work on behalf of the Federation was acknowledged when the Portfolio Secretary (Mr. S. Stewart, F.I.C., Kirkcaldy Ph.S.), and the 1906 Salon Secretary (Mr. Vanessa C. Baird, Dundee and East of Scotland Ph.A.), were elected Vice-Presidents. The Secretary (Mr. John B. MacLachlan), treasurer (Mr. Arch. Campbell), and auditors (Messrs. J. A. Murdoch and R. C. Thomson), were unanimously re-elected. Thirteen delegates were nominated for the Council (nine vacancies), and the ballot revealed the following as elected:—Messrs. H. Coates, Perthshire Society of Natural Science (Ph. Section); R. Milne, Paisley Philosophical Institute (Ph. Section); Dan Dunlop, Motherwell Young Men's Institute C.C.; A. Richmond, M.D., Paisley; J. W. Ross, Brechin, Ph.A.; J. S. Bryce, Pais-

FIG. 5.

ley; D. Horn, Glasgow Southern Ph. A.; A. Symon, Wishaw Ph.A.; E. Darwin Wilmot, Edinburgh University C.C. The rules provide for the addition of not more than three associates, and Mr. James Patrick, Edinburgh, was unanimously appointed the first for that office. Heartly thanks were accorded Mr. Macdougald as chairman, and also for his labours on behalf of the Federation as President. At the Council meeting, Mr. A. W. Mill, President of the Shotts C.C., was unanimously appointed Portfolio Secretary.

The report (abridged) of the secretary, Mr. John B. MacLachlan, is as follows:—

I am happy to be able to report that the Federation still continues to progress; 1904 closed with a membership of 32 societies; in 1905 we have to record 38 societies combined in the Federation for the betterment of photography in Scotland. I might also mention, though it does not come within the scope of this report, other additions for this year, thus paving the way for a further increase. When we look back at the sixteen societies that combined to form the Federation three years ago next week (January 17), we have reason to be proud of the manner in which the Scottish societies have taken up the aims enunciated then, and not only the aims, but also the manner in which the members of the Council, through good report and ill, steadily set themselves to carry out the high ideals placed before them.

The Blue Book has now become a valued feature of the Federation; this year it was enlarged, and the increasing number of advertisements show that its value in this respect is becoming realised by those outside the Federation. It is the duty of all

associates to aid in making it yet more complete and helpful. It might be mentioned that it was found necessary to increase this year's issue to 2,500.

The portfolio, splendidly managed by Mr. Stewart, has already become a feature in the life of the federated societies. The "Macdougald Plaque" (gifted by our esteemed President), awarded for the best print in the portfolio, has been awarded to Mr. A. W. Hill, president of the Shotts Camera Club, who has gifted the winning print to the donor of the plaque.

The Salon at Glasgow was acclaimed by press and public as an artistic triumph, but, unfortunately, in spite of the labours of a devoted committee, allied to the enthusiastic covenor, and the indefatigable industry of their secretary, the financial result was not equally favourable, and we had to mourn a deficit. This, however, only tended to show how real was the interest in the Federation of its many friends—the guarantors made good the deficiency, and the funds of the Federation remained intact. The 1905 Salon does not come within the scope of this report, or I might say much, but no, the blushes of the Salon committee are spared.

All that has been said will show you that the Federation is prospering, and that it is alive to its original aim—the betterment of photography in Scotland. It behoves every associate to do his—or her—utmost to help forward the good cause by every means possible.

#### THE PHOTOGRAPHIC CONVENTION.

##### A WINTER RE-UNION.

The social evening announced some time ago to take place as a winter function of the Photographic Convention of the United Kingdom, was held on Friday last at the Galleries of the Royal Society of British Artists, in Suffolk Street, Pall Mall. In the absence of the President, Professor John Joly, F.R.S., a reception of the guests was held by the president-elect, Mr. E. J. Humphrey. Upwards of a hundred ladies and gentlemen were present, and some fifty cordial letters were received regretting that political and other engagements prevented attendance, and wishing the meeting every success. Among those present were Mr. and Mrs. Alfred Ellis, Miss Effie Ellis, Master Douglas Ellis, Mr. and Mrs. A. Corbett, Mr. A. Seaman and Miss Seaman, Mr. W. E. Dunmore, Mr. J. W. P. Rawlins, Mr. and Mrs. E. J. Humphrey, Mr. A. Holsley Hinton, Mr. A. W. Green, Mr. and Mrs. R. R. Beard, Mr. Hans Müller, Mr. H. Snowden Ward, Mr. E. J. Wall, Mr. F. J. Mortimer, Mr. and Mrs. Hedley M. Smith and Miss Alice Smith, Mr. and Mrs. Charles Winter, Mrs. and Miss Beaumont, and Miss Evelyn Beaumont, Mr. and Mrs. J. Seilor, Mr. George E. Brown, Mr. C. Phipps Lucas, Mr. and Mrs. Walter F. Potter, Mr. Frank Potter and Miss Olive Potter, Mr. and Mrs. Wilfred Emery, M. L. Gastine (Paris), Mr. Martin Jacolette, Mr. H. C. Pharoah, Mr. and Mrs. Robert Meynell, Mr. and Mrs. Robert Dixon and the Misses Dixon, Mr. and Mrs. W. H. White, Mr. A. W. Brooks, Mr. and Mrs. T. K. Grant, Herr E. J. Janssen, Mr. T. A. Scotton, Mr. and Mrs. Ralph Robinson, and the Misses Margot and Janet Robinson, Mr. G. W. Watson and Miss Watson, the Misses Muriel and Olive Gaze, Mr. Alec Simpson, Mr. James Hernaman, Mr. and Mrs. F. A. Bridge, Mr. and Mrs. J. W. Marchant, and the Misses Marchant, Mr. and Mrs. Sydney Keith, Mr. William Grove, Middles. Louise and Marie Ferraris, Mr. J. L. Wade, Mr. and Mrs. J. L. Wade, junr., Mr. W. Wade, Mr. P. R. Salmon, Mr. W. Stiles, Mr. Alexander Mackie, Mr. W. S. Killman, Mr. and Mrs. Battams, Mr. and Mrs. Fraser Black, M. Paul Berton, Mrs. McLean, Miss Gobell, Miss Hilda Harding, Miss Frenie Harding, Miss Margot Severn, Mr. J. A. Bovett, Dr. Harrison Orton, Mr. Dance, Mr. Ernest Marler, Mr. E. J. Walker.

The evening was interspersed with an attractive musical programme, arranged by the secretary of the Convention, Mr. F. A. Bridge.

At ten o'clock, a "little dance" was held, Mr. Alfred Ellis and Mr. Walter Potter acting as M.C.s. The whole proceedings, which throughout were of a most enjoyable character, were brought to a close by the singing of the National Anthem, and cheers for Mr. Walter Potter, from whom the suggestion of the evening had emanated.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."*

The following applications for patents were made between January 1 and 6:—

**PRINTING APPARATUS.**—No. 43. Improvements in photographic printing apparatus. Joseph Halden, 17, St. Ann's Square, Manchester.

**COLOUR PHOTOGRAPHY.**—No. 54. A process for the manufacture of a photographic printing paper with which several-coloured photographs can be produced from a single negative. Frank Athron, 11, Clifton Road, South Norwood, London.

**NOVEL EFFECTS.**—No. 91. Improvements in the art of photography and the production of novel and striking effects by photographic means. Hiram Codd, Joseph Deeks, 1, Queen Victoria Street, London.

**MACHINE COPYING.**—No. 235. Improvements in electrically operated photographic copying apparatus. Otto Lienekampf, 31, Bedford Street, Strand, London.

**CAMERAS.**—No. 405. Improvements in photographic cameras. The Thornton-Pickard Manufacturing Co., Ltd. George Arthur Pickard and Frank Slinger, 6, Bank Street, Manchester.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**RELIEF PHOTOGRAPHS.**—No. 5,559, 1905. The invention consists in the taking of a positive from the negative of the subject, the positive and negative being then superposed and a third photograph being taken of the pair thus superposed whilst their picture surfaces are displaced. This third copy is then transferred to stone or plate for printing in apparent relief. In the production of the third plate from the superposed negative and positive, the shifting of the negative and positive takes place, during exposure, by any micrometer screw arrangement. The copied picture on the third plate is not, however, employed as in the known processes for producing independent relief pictures with raised or sunken outline, but is used for the production of a printing block. This block is used for printing, and a picture is obtained therefrom which gives an appearance of light and shade effects as if in actual relief. To obtain delicate blended effects of light and shade upon the third plate, the first and second plates are laid one upon the other, so that the picture outlines are first coincidental, and the displacing of the one plate against the other is only effected during the exposure. The high appearance of the reliefs and the breadth of the shades also depends upon the degree of displacement of one plate with relation to the other. In similar manner, quite different reliefs can be produced having very fine light shades or strong coarse shades for instance, according as during the exposure the plates are shifted little or much. The most diverse appearances of relief or intaglio for prints can be obtained, according as the plates are brought with the film or plain glass surfaces together. As the time of exposure is as a rule fixed, so would the degree of displacement and naturally also the quickness of displacement be influenced. The transferring of the third pictures to a printing plate, stone or the like is effected as in the known processes of zincography and lithography. Pio Baruffi, 13, Via Gomberti, Bologna, Italy.

**DAYLIGHT DEVELOPMENT OF FILMS.**—No. 28,594. The invention consists of a long strip or band, which is provided with corrugations along each edge, and is wound on a cylinder to which it is attached. When wound, caps enclose the coil at each end, forming a light-tight case enclosing the film. The figures show a modified form of the instrument in which the coilable strip B need not be of any greater length than the photographic film G. Its projections  $b^1$ ,  $b^2$ , are shown as arranged on that side which will be the inner side when the strip is coiled, and the photographic film is laid against the outer side with the sensitized side outermost. The cylinder A may be provided with flanges  $a^3$ ,  $a^4$ , and

these will be advantageous as guides in rolling up the coillable strip and photographic film, in either form of the invention. The reel comprising the cylinder A may be kept in proper position lengthwise of the receptacle in which it is used by means of

posts,  $c^8$ , attached to the cap  $C^2$ , and by posts  $c^9$ , attached to a light shield,  $c^{10}$ , which is fastened on the cap  $C^1$  by means of spurs or fingers extending from its periphery. In each form of the invention the cylinder on which the coillable strip and photographic film are wound, and all appurtenances of that cylinder,

are provided with a case. They form a reel and are closed to light without any provision for being operated from outside the case. H. H. Lake, for Charles Harris Shaw, 637, Putnam Avenue, Brooklyn, New York, U.S.A.

**DIRECT-VISION FINDER.**—No. 22,259. The claim is in regard to a finder of the direct-vision form in which the picture is viewed in a frame provided with cross-wires, a sight being used in the form of the usual upright bar behind the cross-wires. The invention consists in the automatic folding down of the sight when the frame is turned down after use. In the figure, 1 is the frame for the sighting cross which is fixed in its open and

closed position by a spring 4, and 5 is the sight. On the part 1 of the frame a pin 7 revolvable in lugs 6 is mounted the free end of which pin extends to the foot 8 of the sight. Now as soon as the frame is folded up the pin 7 is displaced to the extent of the arc of a circle described by its pivot and encounters the foot 8 of the sight, whereby this is caused to be folded down against the action of a spring 9 and then comes under the folded down sighting cross. Gustav Geiger, 16, Maximilian Platz, Munich, Germany.

**DUPLEX CINEMATOGRAPHY.**—No. 29,051. The claims are for a system of, and apparatus for, cinematographic projection, to which are employed a duplex projecting system and a pair of projecting lenses, the images from which are thrown upon coincident positions on the screen. There is an arrangement of shutters or their equivalents, so constructed that when the picture projected from one lens is fully exposed, the next picture in succession projected from the other lens is fully obscured, and when only a portion of one picture is exposed, the corresponding portion of the other picture is obscured and the remainder exposed; or alternatively there may be provided an arrangement of shutters or their equivalents so constructed that when the picture projected from one lens is fully exposed, the next picture in succession, projected from the other lens, is fully obscured, and while one picture is being gradually obscured, the next picture in succession is being gradually and in exactly the same ratio exposed, so that the totals of the portions of the pictures thrown or projected on the screen by the lenses amount to but never exceed one complete picture, and throughout the whole operation there will be a continuity of picture projected and there will be no decrease or obscuration of light whatever, and at all times during actual exposure the film containing the exposed picture or the films or parts thereof containing the exposed picture or the films or parts thereof containing the partially exposed pictures, will remain absolutely stationary and steady. The inventor does not confine himself to a duplex projecting system, as a triplex or multiplex system may under certain circumstances be found desirable. Robert Thorn Haines, Swanston Street, Melbourne, Victoria, Australia.

The following patent is open to inspection before acceptance under the Patents Act, 1901: Process and apparatus for the production of photographs. Dischner.

## Exhibitions.

### THE SCOTTISH SALON.

THE third annual exhibition of the Scottish Salon opened at the Victoria Art Galleries, Dundee, on January 13 last, and will remain open until February 3. The present Salon is noticeable for the strong representation made by the profession. It has frequently been said that the amateur is usurping the exhibitions, and that the professional is being quietly shelved. As the prominence given to the work of the professionals struck us, as well as the high quality of that work, it might well be treated of here, as that is a side of the Salon that in all probability will escape attention.

The work of the professional is hedged round by many conventions and many difficulties, unknown to the free amateur, who can work as he is inclined and follow where fancy leads—he has no crotchety clients to please, nor prints to have ready within a specified time. The photography of the man in the profession, guided and hemmed in as it is, is, therefore, mainly run on academic lines—he does not try the *outré* effects his more independent brother may; hence we may find much to please, but, as a rule, nothing to startle.

But first a word as to the Salon itself. The hall is specially built for art exhibitions, all lit from the roof, and on the walls (coloured dark terra-cotta) the committee have placed panels of jute in a natural brown tint, bordered by a wide strip of undressed and unstained wood. The effect is at first somewhat startling, but it gains on one; the broad border effectively separates the desert of wall space above from the picture screens, and, at the same time, from its "natural" blending with the natural colour of the fabric background, injures none of the pictures.

The large and influential attendance at the opening by Sheriff Campbell-Smith, LL.D., testified to the interest taken in the art. The Salon, offering, as it does, no prizes, has a special appeal to the man who has his living to make by his art, as all pictures hung are, as far as anything to the contrary is indicated, of equal merit, and one professional does not have the chagrin of receiving a bronze plaque, while his more humble brother down the street, with a less fashionable clientèle, is awarded a silver one.

The giants are there, the smaller man is also there; all combine to form a splendid show. J. Craig Annan, Glasgow, has three pic-

tures hung, including one new to exhibitions, a portrait of the actress "Ailsa Craig," a lesson in the treatment of drapery, the graceful flowing lines of the dress all leading upward to the artistic intellectual face. William Crooke, of Edinburgh, is represented by five examples of his powerful and characteristic portraiture. That of Miss Leslie St. John is a full-length figure of a lady in walking costume, which exhibits a very clever subordination of the surroundings to the features, though the reproduction in the catalogue gives a poor idea of the actual picture.

James Auld, Edinburgh, shows good satisfactory work. W. D. Brown, Lanark, departs from the beaten track a little, and shows an interior of a stable—hard a little, but wonderful, when the difficulties are considered. George L. A. Blair, Paisley, is mainly represented by landscape—he is the anomaly of a professional who is an enthusiast in gum-bichromate—his "Stormswept" is a specially strong bit of work. J. Bruce Cameron (Kirkintilloch) goes outside to the common things of life for subjects, his "The Water-cart" being honoured by reproduction in the catalogue. In Dan Dunlop (Motherwell), a professional secures the honour of having the largest number of pictures hung, his fifteen pictures out of the 302 giving him 5 per cent. of the whole exhibition—a truly marvellous percentage. His subjects range from portraiture, architecture, to flowers, and we were particularly struck with the delicacy of some of his flower studies. His seems to be a real case of a man's profession being his hobby, for on the walls we saw a picture which has gained awards, and was taken when on his honeymoon! Wm. Mitchell (Selkirk) is represented by one picture; John Moffat (Edinburgh) has two pictures; one of them, "The Dance," is probably the most popular picture in the hall. It is an object lesson on the satisfactory and artistic grouping of children. P. D. Nairn (Stirling) has three pictures, one especially attractive of sand-dunes. Andrew Paterson (Inverness) has five pictures hung, one being an example of dramatic portraiture. James Patrick, who, by the way, was honoured at the annual meeting by being elected the first associate member of council, includes in his contribution a really artistic portrait of an artist. John Patrick (Edinburgh) exhibits his powerful portrait of Carlyle, a picture that drew from the learned sheriff who opened the Salon high commendation. He had known and conversed with Carlyle, and he preferred Patrick's portrait to the celebrated painting by Whistler as giving a truer representation of the man. J. M. Silver and John Steele (of Brechin) are both represented by honest work. The name of Peter G. Terras (Markinch) in the catalogue calls to mind the delightful genre pictures associated with Terras (of Markinch), and we have an echo of these in "Tiddlewinks." J. M. Whitehead (of Alva) is one of our most distinguished workers, and one whose pictures always strengthen any exhibition. His work, while strongly artistic, never lacks technical perfection, such a perfection as is always associated with the heroes of olden days. "Until the day break and the shadows flee away" (reproduced in the catalogue) is a telling example of a sentiment completely and yet simply expressed; while the peaceful calm of "On the clear, winding Devon" is fittingly portrayed. E. Drummond Young (Edinburgh) only sends one example, but it is an excellent example of portraiture.

Nowhere in Scotland can such a comprehensive collection of the photographic work of the country be seen as at the Salon, and we would strongly advise all who have any interest in the improvement of their work—and the man who has not should quit it or die—to visit Dundee and study the work of the masters.

Fain would we treat of the many exhibits by amateurs, but space will not permit here.

The "foreigner" in this year's Salon is Mr. Fredk. H. Evans, whose versatility is represented by twenty-three photographs selected from his portraiture, figure studies, landscape, and architecture. The latter is in a liberal majority, though, much as we admire Mr. Evans's architectural photography, we would have wished for more of the landscape and seascape, of which, we think, he exhibits too little.

The Federation deserves every credit for organising and carrying through this artistic treat. The "Henry Coates Challenge Shield" was won by the Grangemouth Photographic Association, second place being taken by last year's winners, Paisley Philosophical Institute (Photographic section), and Aberdeen Photographic Art Club taking third place, while one of its members (James Clerihew)

entered the best individual slide in the whole competition. The associates' competition for the best set of three slides was won by Robert Marshall, the energetic secretary of Grangemouth Association, Robt. M. Steel, convener of the lantern section of the Paisley, coming second. The judges were Messrs. Ezra Clough, Bradford; Alex. Keighley, Keighley, and Godfrey, Bingley, Leeds; the arrangements being kindly carried out by Mr. Clough. The "Macdougald Plaque" (gold), presented by Mr. Macdougald, president, for the best print in the portfolio was gained by Mr. A. W. Hill, president of the Shotts Camera Club, with his print "The Bo'sun."

At the luncheon which followed Mr. Macdougald presided, the croupiers being Messrs. J. W. Eadie and D. Horn, vice-presidents. Mr. Eadie proposed the toast of "The Scottish Photographic Federation," and expressed the hope that the expansion of its membership would continue, and its usefulness increase. The secretary, in reply, pointed out that the year had opened well, three societies having already intimated federation. "The Salon Committee" was honoured on the call of Mr. Horn, who spoke of the immense amount of work entailed on the committee, and complimented them on the completeness of their arrangements. The Chairman, in reply, spoke of the unanimity with which they had worked together.

## New Books.

"The Modern Way in Picture-making." (London: Kodak, Limited, 4s.)

Strictly modern in its outlook on photography, this handsomely produced volume should stimulate as well as instruct the amateur photographer. It treats frankly of the Kodak system of film and plate photography, and devotes a number of pages to the manipulation of printing papers issued with the hall-mark of the Eastman Companies. Nevertheless, there are large sections which can be read with profit by any photographer to whatever goods he may pin his faith. Portraiture by flashlight is treated by Mr. W. S. Ritch, who accompanies his precept with a whole series of good examples of his work. Mr. Alfred Stieglitz writes on platinum printing and on simplicity in composition; Mr. Rudolf Eickemeyer jun., speaks of and illustrates his work in the photography of winter scenes; whilst a writer unknown to us (A. Radclyffe Dugmore) deals in like manner with natural history photography by means of a Kodak. We have also M. Demachy on "gum," and Mr. J. H. Sinclair on carbon—in all a goodly company of the authorities. There are other unsigned articles on enlarging, developing, and printing, and though the arrangement of the volume is somewhat unsystematic, the contents form a big budget of practical information which we can quite recommend to the amateur who wants not only advice on how to proceed but some example before him of what is a desirable result.

A GERMAN list of trade names has been issued from the office of our contemporary, "Die Photographische Industrie," as a guide to the sources of supply of articles marketed under fancy names. The list is arranged in alphabetical order of the names, and to each entry are appended the name of the supplying firm and an indication of the character of the article, thus: "Velocam. Ernemann, Dresden. Camera." We notice one or two entries of quite obsolete goods, and, curiously enough, the compilers have omitted the word Kodak, though they include other trade names of the Eastman Companies. The list may, however, be of occasional service to British members of the trade in locating the commercial source of manufactured articles.

## CATALOGUES AND TRADE NOTICES

THE annual stock-taking list of the Tella Camera Co., of 110, Shaftesbury Avenue, London, W., which has just reached us on publication, runs to thirty-six pages, and includes a great variety of apparatus brought together through the active operations of the Company in its special line, that of exchanging cameras, and other apparatus.

THE City Sale and Exchange, 81, Aldersgate Street, E.C., send us an extensive list of secondhand and shop-soiled goods, chiefly hand,

field and studio cameras and lenses, which are listed at low prices, and can also be obtained at on instalment terms.

AN annual clearance sale of cinematograph films is now being held by the Charles Urban Trading Company, 48, Rupert Street, W., by whom has been issued a long list of subjects, which are offered at prices of 2½d. and 3d. per foot. Of the new films of the Urban Company two notable ones are, "What is whiskey?" showing every phase of the manufacture from the barley field to the West End, and "The Sherborne Pageant," recently arranged by Louis N. Parker.

## News and Notes.

It is announced that the photographic business of Miss Kate Pragnall has been taken over by Miss Alice M. Stewart at the same address, Court Studio, 39, Brompton Square.

**PHOTOGRAPHIC Trade in South Africa.**—The "British South African Export Gazette," in commenting upon the exhibition now being held at Cape Town, names the figure of £70,000 as the value of photographic materials imported annually into South Africa.

**ELECTION Business.**—Events have proved the greatly increased use which has been made of photography in the present General Election. To quote the "Chronicle":—"No candidate's address is complete without his portrait, which is, naturally enough, made to look as attractive as possible. If the candidate is blessed with a beautiful wife he should have no hesitation in adding her picture as well, and some even go the length of throwing in the portrait of a son or daughter if young and pretty enough. The man who is asking for your suffrages generally employs a photographer nowadays to 'take' him when he is addressing the electors, and if the result gives a favourable impression of his eloquence he sends it to the illustrated papers."

Mr. S. B. HORD, who for some years past has been editing the "Photographic Times," and also the "American Annual of Photography," while also employed with the Folmer and Schwing Manufacturing Company, has just accepted a position as assistant to Mr. L. B. Jones, Advertising Manager of the Eastman Kodak Company in America.

**COLOURS for Picture Postcards.**—A correspondent of the "Pharmaceutical Journal" writes:—"Being personally acquainted with one of the largest producers of picture postcards in the South of England I can give every particular necessary for tinting monochrome or mezzotint cards; these, of course, must not be confounded with those produced by the "oleo" process. In the first place a camel hair pencil is only used for spotting, practically all the colouring being done with an "air brush," which is nothing more than a fine spray. The colours used by them are three in number, the simple primaries: "yellow," an aqueous solution of gamboge; "blue," an aqueous solution of indigo with oxalic or other acid; and "red," a solution of dragons' blood in methylated spirit—this is always used first. Aniline dyes are never employed, being too fugitive for exposure in a shop window.

**The Aerograph New Premises.**—Those interested in the modern developments of the method of colouring and decoration which are familiar to almost all photographers in the "Aerograph," should pay a visit to the new premises in which the Aerograph Company has established itself at 43, Holborn Viaduct, London, E.C. We had an opportunity last week of seeing in operation the latest machine process of colouring by the method which Mr. Burdick has recently brought to perfection and which his firm is now offering in competition with lithography and other crafts. For moderate editions the "Aerograph" system can compete very advantageously with litho or typographic three-colour in the production of coloured postcards, window bills and tickets, etc., and those interested will find it worth their while to examine the work in these and other departments which is now being produced.

SOME water colours of "Animal and Pastoral Subjects" by Mr. J. C. Dollman (who is down to lecture on "The Artistic in Painting and Photography" at the Society of Arts shortly) are to be seen at the galleries of the Fine Art Society. They have (says the

"Globe") a distinct charm as dainty transcriptions of nature treated with much acuteness of observation and with a very delicate feeling for subtleties of aerial colour. They are not wanting in variety; and though they attempt no aggressive departure from the older water colour tradition they have a pleasant individuality. The best of them are the subtle landscapes "Spring Sunshine" and "A Hazy Afternoon," the strong and breezy sketch, "Summer," and the twilight scene, "On the Road." There is also much dramatic power in the small figure subject, "Enoch Arden."

AMBER bottles for chemicals was the moral of a paper before the Sheffield Pharmaceutical and Chemical Society last week by Mr. F. A. Upsher Smith, who pointed out the beneficial effects of excluding the actinic rays of light from many bodies which are not commonly accused of notable sensitiveness to light. A list of these substances was given, and among other reasons for the adoption of the amber bottle for the storage of chemicals was the one that the amber glass is free from lead and therefore that certain solutions, such as those of ammonium acetate and citrate, are better preserved in such receptacles.

## Commercial & Legal Intelligence.

**LEGAL Photography.**—A case illustrating the advantage of the camera came before the Rye County Magistrates last week, when a cattle dealer was summoned for using a gun without a licence. A pigeon and starling shoot was held at Playden, and the defendant was one of the marksmen. From the evidence of the Inland Revenue officer, it appeared defendant had not a licence, and he denied being present at the meeting. The officer, however, or rather some person working in conjunction with him, had taken a "snapshot" of the party and this proved conclusively that the defendant was present. The result was that defendant subsequently admitted being present, and was mulcted in a fine of £1, and ordered to pay the costs.

**A POSTCARD Order.**—James William Humphreys, photographer, took his trial at the Wilts Quarter Sessions last week, for obtaining various sums of money from various persons, including Mr. Hibberd, of Heytesbury, by false pretences. In about sixteen weeks, prisoner received orders for 50,000 picture postcards, and took £113 2s. 9d. To appease the pressure of tradesmen, to get their orders executed, he sent small quantities of the cards, but they were so bad that they were promptly returned. He admitted that he had neither the apparatus nor the means of executing the orders. His "studio" was a small cottage at Blandford, with a small tin dark room behind. For the defence it was stated that orders were not given on the strength of the prisoner's statement, but in the first place, on the strength of a reference from a Salisbury firm, and secondly because people who were known to the plaintiffs had given the man orders. The jury returned a verdict of "not guilty" and acquitted the prisoner.

**A PALTRY Case of L.C.C. Interference.**—Mr. Paul Taylor had before him last week a summons by the London County Council against Hermann Ernst, a photographer, of 14, Finchley Road, for retaining a photographic show-case on the forecourt of his premises without having obtained the approval of the Council. It seemed that the Council discovered the existence of the show-case in June, 1903, and granted the defendant permission to retain it on condition that he removed it at the end of two years. He agreed, but when the two years expired he merely removed it to another position on the forecourt and placed it upon wheels. The Council asked that it should be removed. Mr. Paul Taylor, after examining a photograph of the premises, said the show-case seemed to him to be a distinct ornament to the place, and it relieved the monotony of the dull, ugly frontage. What, he asked, did the Council object to? Mr. Dimes replied that the London County Council took the view that structures of that kind were detrimental to the neighbourhood, and there was no knowing where they would cease if the Council did not exercise their control. Mr. Taylor: He is a photographer, and is not allowed to have a show-case on his own forecourt. Is it really suggested that that is a matter which ought to be prevented in a great city like London? It almost takes my breath away to hear such a thing. The summons was eventually adjourned sine die.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
19.....	Aberdeen Amat. Photo. Assn.	Lantern Exhibition. Mr. Bearsley.
19.....	Sutton Photographic Club .....	"Eclipse Photography." Mr. C. Thwaites.
19.....	Watford Photographic Society	"Orthochromatic Photography." Mr. E. Robins.
22.....	Scarborough and Dis. Ph. Soc.	Members' Night. "Intensification and Reduction of Negatives."
22.....	Acton and Chiswick Photo. Club	"Toning Bromides." Mr. J. H. Avery.
22.....	Dewsbury Photo. Society .....	Yorkshire Photographic Union Members' Portfolio.
22.....	Cripplegate Photo. Society .....	"Nine Thousand Miles in Five Weeks." Mr. R. Child Bayley.
22.....	South London Photo. Society ..	"Photographic Papers and Toning." Mr. H. B. Edmunds.
22.....	Bowes Park and Dis. Ph. Soc.....	"Lantern Slide Making." Mr. F. P. Bayne.
22.....	Southampton Camera Club .....	Photographic News Prize Slides.
22.....	Hastings and St. Leonards P.S.	"Something New." Demonstrated.
22.....	Wallasey Amat. Photo. Soc.	Members' Question Night.
22.....	Wildnes Photographic Society.....	Amateur Photographer Prize Slides.
22.....	Heaton & Dis. Camera Club.....	"Photographic Survey Work." Mr. G. D. Rose.
23.....	Royal Photographic Soc. ....	"Artificial Light in Portraiture." Demonstrated. Messrs. Houghtons, Ltd., and the Boardman Electrical Patents Co., Ltd.
23.....	Nelson Photographic Society ..	Colne Camera Club Visit Nelson Photographic Society.
23.....	Sheffield Photographic Society	"The Beginner in the Dark Room." Mr. J. W. Charlesworth.
23.....	Newcastle-on-Tyne Photo. Assn	Members' Enlarging Night.
23.....	L.C.C. Staff Camera Club .....	"Sulphide Toning of Bromide Papers."
23.....	Gloucestershire Photo. Society	Members' Lecturette.
23.....	Manchester Amat. Photo. Soc.	"Marine Photography." Mr. F. J. Mortimer.
23.....	Colne Camera Club .....	Visit to Nelson Photographic Society.
23.....	Birmingham Photo. Society. ...	"Lantern Slides." Demonstrated. Mr. S. L. Coulthurst.
23.....	Sunderland Camera Club .....	"Rambles with a Gamekeeper." (With Some Photographic Reminiscences.) Mr. Percy Mail.
23.....	Darlington Camera Club .....	"How to Make Enlarged Negatives." Dr. Martin.
23.....	Otley & Dis. Cam. & Art Soc.	"Velox and its New Applications." Mr. W. Sadler.
23.....	St. Helens Camera Club .....	Annual Meeting.
24.....	North Middlesex Photo. Soc. ...	"Photography with a Hand Camera." Mr. W. Thomas.
24.....	Coventry Photo. Club .....	"Tinting Development." Mr. M. W. Danks.
24.....	Edmonton and Dis. Photo. Soc.	"Flower Photography." Mr. A. J. Linford.
24.....	Halifax Camera Club .....	"Birdnesting with a Camera." Mr. Riley Fortune.
24.....	Leeds Camera Club .....	"Places and People in Westmorland." Illustrated. Mr. Percy Lund.
24.....	Everton Camera Club .....	"Photographic Lens Making." Messrs. Taylor, Taylor and Hobson.
24.....	G.E.R. Mechanics' Institution.....	Lantern Evening. Mr. A. Woolford.
24.....	Acton Photographic Society .....	"Pinhole Photography." Mr. H. G. Green.
24.....	Cricklewood Photo. Society .....	"Bromide Toning." Mr. J. H. Avery.
24.....	Liverpool Amateur Ph. Assn.....	"Yorkshire Minsters Ripon, York and Beverley." Mr. C. B. Howdill.
25.....	Hull Photographic Society .....	"Holidays—Photographically." Mr. W. H. Willatt.
25.....	Harrogate Camera Club .....	"Photo-Ceramics." Demonstrated. Mr. J. Skilbeck.
25.....	Darwen Photographic Assn.....	"The Toning of Bromide Prints." Mr. W. Duxbury.
25.....	Leek and District Photo. Soc.....	Trimming and Mounting Competition.
25.....	Tring Camera Club .....	Last Day for Delivery of Prints for Annual Exhibition.
25.....	Rodley, Farsley, & Calverley Dis.	"An Old Printing Process." Mr. F. W. Machen.
25.....	Woolwich Photographic Soc. ....	Open Night.
25.....	London and Prov. Photo. Assn	"Sketching with a Camera." Mr. W. R. Stretton.
25.....	Richmond Camera Club .....	"English and Continental Collotype Compared." Mr. F. R. Witthaus.
25.....	Bolt Court Sch. of Photo. Eng.	Exhibition in Town Hall.
25.....	outh Essex Camera Club .....	

**SUTTON PHOTOGRAPHIC CLUB.**—Mr. Hector Maclean, F.R.P.S., in his capacity as chairman of the Sutton Photographic Club, gave, at the Public Hall, Sutton, on January 12, a lecture on "Photography as a Pastime" as introduction to a course of free instruction lectures upon elementary photography which has been arranged by the club. Much merriment was caused by two owls which were successively shown—the first, of long proportions, wearing an expression of philosophic doubt, was dubbed "Balfour," while the second, of portly outline, with eyes wide open and beak eager for

the fray, seemed the very prototype of a birdland Campbell-Bannerman. In an interval Mr. A. P. Hoole was successful in showing on the screen, by means of a chemical tank, the development and fixing of a dry plate, the action of Farmer's reducer, and the changing of a brown uranium-toned slide into a blue one.

**ABERDEEN PHOTO-ART CLUB.**—At a meeting of the club last week an illustrated lecture on "Marine Photography" was given by Mr. W. Findlay, mostly in carbon. The majority of the pictures were taken in early morning. At the close of the lecture the president intimated that the club had secured the third place at the Scottish Federation Salon for a set of eighteen lantern slides, while one of its members, Mr. James Clerihew, stood first for the best slide sent in by societies in this competition.

**CROYDON CAMERA CLUB.**—Mr. H. Creighton-Beckett, on the 10th inst., gave a most interesting and highly instructive lantern lecture, illustrated by about 170 slides. Rarely indeed has such a magnificent set, judged either from a technical or pictorial point of view, been shown in the club-rooms, and it is a matter of regret that the excellent explanatory descriptions and expositions of what to do and what to avoid do not readily admit of condensation. Dealing with the kit, the lecturer advised the employment of the best lens the pocket could afford. He preferred the square form of camera, and for fine focussing utilised "the aerial image" by cementing microscopic cover glasses to the ground-glass screen. For general use, a half-plate camera was perhaps the best, as it gave a fair-sized direct picture, which could conveniently be enlarged or reduced. It was also useful to fit an extra reversing back, to take quarter-plate slides, either half or quarter plates being used, according to the importance or nature of the subject. The best all-round plate to employ was undoubtedly a slow one, generously coated and backed. Personally he did not favour exposing by meter, but based his exposures on past experience, a full note giving all necessary particulars being recorded in each case.

**BURTON-ON-TRENT NATURAL HISTORY AND ARCHEOLOGICAL SOCIETY (Photograph Section).**—At a meeting held on January 9 a demonstration was given by Mr. Ernest Abrahams on "The Reflex System of Hand Cameras," illustrated by the "Videx." The demonstrator pointed out the great advantage possessed by these cameras in focussing up to the moment of exposure. The image from the lens is reflected by a mirror at an angle of forty-five degrees in the body of the camera on to the focussing screen at the top of the camera, the image appearing the right way up and not, as usually, reversed. The button which releases the focal plane shutter automatically lifts up the mirror to the top of the camera, thus allowing the plate to be exposed. A number of excellent prints from negatives taken with the "Videx" by Mr. Abrahams himself were shown at the conclusion of the meeting.

**BOWES PARK PHOTOGRAPHIC SOCIETY.**—The annual general meeting was held on Monday last, when the following officers and council were elected—viz.: President—Mr. A. J. Craston; vice-presidents—Messrs. W. T. P. Cunningham and E. H. Young; treasurer—Mr. A. Bird; secretary—Mr. H. C. Bird; librarian—Mr. C. S. Carr; council—Messrs. W. H. Carpenter, E. H. Down, A. F. Hawes, F. C. Hornsey, H. Oliver, C. W. Peacock, and E. Tappenden. The council's report showed that the society was in a very flourishing condition, the membership now numbering 100. To commemorate his term of office, the late president (Mr. R. Core Gardner) has presented to the society a silver challenge bowl for competition amongst the members, to be won twice to become the property of any member.

**ROYAL PHOTOGRAPHIC SOCIETY.**—The following new Fellows have been elected by the council:—Dr. Hans Harting, Arthur Marshall, A.R.I.B.A., Thomas Lee Symms, Harry Oscar Klein, Walter Longley Bourke, Andrew James Fuller.

A HOUSE exhibition of the work of Alvin Langdon Coburn will be opened at the Royal Photographic Society, Russell Square, on Monday, February 5. The collection will include examples of all kinds of the photographic work—landscape, portraiture, etc.—with which Mr. Coburn has been associated in recent exhibitions, particularly that of the Photographic Salon.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE POSTCARD CULT. To the Editors.

Gentlemen,—Allow me to take exception to your reference to the picture postcard as "this modern scourge of middle-class society." I grant that there is a large proportion of poor and indifferent postcards on the market, but at the same time there is a vast number of beautifully printed cards of high artistic merit, the only thing "cheap" about them being the price. Postcards are now published from the best of paintings, and the greatest skill of the printer's art is lavished upon them, resulting in a production which is a genuine delight as well as proving a decided boon of an artistic educational advantage. The quality of the work has assured a position for the picture postcard, and a position which has been well earned. It only remains for postcard publishers to produce the best of work to retain that position, and I enclose for your acceptance a pack of local postcards showing the kind of card I publish.—Yours faithfully,  
 Southwold, January 13, 1906.

F. JENKINS.

[Our reference was not intended to refer in any way to the quality of the postcards on the market. We had in mind the social obligations which the postcard cult lays upon those moving in certain circles of society, not only in its levy of contributions to swell the albums of collectors, but in the enforced interest which the visitor to a house must be prepared to display in a long series of disconnected pictures. The cards sent by our correspondent are admirable examples of high quality in production.—Eds. B.J.P.]

### PHOTOGRAPHERS AND ELECTION RESULTS.

To the Editors.

Gentlemen,—It's an ill wind that blows nobody any good, and there is no reason why professional photographers should not take advantage of the present election to recoup themselves, even if in only a small way, for the temporary stagnation of business that it produces. In many towns the local paper or the election agents utilise the optical lantern for projecting portraits of the leading politicians, interspersed with hastily written statements of the results of the polling.

Now, there is no reason why professional photographers should not undertake this, for all know, or should know, how to manipulate a lantern, and if, besides, they prove that they can prepare in a minute or two written slides, there ought to be a chance for a little business.

It is, of course, out of the question to get the results set up in type and make a negative and project that, but by means of one or two well-known dodges any announcement can be prepared in less than five minutes.

In the first place, such announcements are usually shown on a screen hung up in a window. Now, as the results are seen by the populace through the screen it is essential that this be as transparent as possible. Tracing cloth, which is the best thing, may not be large enough; then the next best thing is white linen which has been well washed to free it from the dressing. The thinner this is the better; calico is too coarse.

There is one point which must not be overlooked—namely, to calculate out what should be the width of the slide so that the whole of the announcement may appear on the window screen. Attention is drawn to this because, as a rule, in such work one is hampered by want of working distance between lantern and screen, or else by the narrowness of the window.

There are two methods of making announcements: one in black on white ground, and the other the reverse—namely, white letters on black ground. A taking method is, of course, to use a science lantern and reversing prism and project the writing as it is done. This may possibly, however, be an unnecessary refinement.

If the idea is to show black letters and figures on a white ground, there is no difficulty in providing oneself with a dozen or two of squares of ground glass and using these—that is, of course, if but a few announcements are to be made and there is a chance of clearing the glasses in between the shows. Another method is to coat

$\frac{3}{4}$  squares of plain glass with a matt varnish, and the following is very satisfactory:—

Gum sandarac .....	10 grains.
Gum mastic .....	10 grains.
Ether .....	1 ounce.
Dissolve and add	
Benzole .....	96 minims.

This dries very rapidly, and a gross or two of plates may be prepared in advance. The announcement is written on this surface, and then it is flowed over, if thought desirable, with the following, which makes the ground perfectly transparent:—

Gum sandarac .....	15 grains.
Gum mastic .....	15 grains.
Ether .....	1 ounce.

This also dries very rapidly. There is, however, one precaution to take—namely, the great danger of an explosion through the contact of the fumes of ether with a naked light.

Now a hint as regards the writing medium. Do not be afraid to write thickly. Use a BBBB or BBBBBB lead pencil. If you want to use the colours of the local candidates, then use soft crayons well pointed, and have a good stock, so that when one breaks there is another ready.

If you want to project white letters on a black ground, a style which is easier to read, all that is requisite is the coating of  $\frac{3}{4}$  squares with a matt black varnish, which will take the needle or graver point well. Here, again, we must give the caution to avoid fine writing. Write boldly and thickly; never mind the criticism that your upstrokes and downstrokes are the same thickness. The crowd are more prone to try the thickness of each other's skulls than criticise your fine upstrokes, and the bolder you write the better and the further can the results be seen.

There are a lot of formulæ extant for making these black varnishes. The following, however, is simple.

Thick linseed oil .....	1 part.
Crushed peach black .....	4 parts.
Spirit of turpentine with 1 per cent. manganese resinate .....	5 parts.
Ether .....	15 parts

This varnish is applied like collodion, and dries in twenty-four hours. It is in the most satisfactory condition for writing on within forty-eight hours of coating, and is then removable in clean sharp lines.

Now, if you want to show coloured letters instead of white, make a fixed cover glass of bright ruby and bright cobalt blue glass, one-half the one and the other half the other. Bind these together firmly at the sides, then when the blues are on top you can use the blue to cover their number, and when the reds win simply reversing the cover glass shows the blues down under, and if you allow enough room so that the joint always falls between the lines of writing the result is effective.

It is, of course, quite easy to use strong spirituous solutions of aniline dyes and just paint over your white letters, but the solutions must be thickened with dextrine and be very strong, whereas by using coloured glasses there is nothing to paint on, nothing to dry, and with a little ingenuity the colours can be fitted to the announcements without more trouble than making the cover glass and reversing it according to whether the blue or red comes out on top. I hope your readers may find these few hints of use to them. Yours very truly,

MARSHALL BAIN.

January 12, 1906.

### SULPHIDE TONING OF SILVER PRINTS.

To the Editors.

Gentlemen,—The article under the above heading on page 28 of the last issue, by Mr. Jarman, contains some points which are, I think, open to strong criticism.

In the first place, the directions given to plunge the prints without washing into the hypo solution is more than likely—in fact, almost certain—to give rise to the very sulphurisation which the author apparently condemns, as any one can at once prove by treating a print in this way for a short time and then applying his nose to it, and he will be able to at once detect sulphuretted hydrogen or sulphurous acid, or both. The effect of these on the silver image is disastrous.

The combined bath given is also in prime condition to cause sulphurisation, as proved by the precipitation of the sulphur, for Lumière, Seyewetz, and Chicaudard and Valenta have proved that acids and alum in a combined bath give rise to a continuous evolu-

tion of sulphuretted hydrogen and sulphurous acid with the formation of acid sulphite of soda, and deposition of sulphur. I venture to say, therefore, that the "sulphide plus gold toning" is gold plus sulphurisation, notwithstanding the fact that the writer of the article has porcelains thus treated which are six years old. The conditions of a paper print and a porcelain are not the same as regards permanency, for no consideration is taken of the presence of the paper and baryta film.

True, sulphide toning is an old dodge, and when properly carried out perfectly reliable. I have practised it certainly for fifteen years, and the proper way to set about it is as follows:—Immerse the prints as they come from the frames in a 10 per cent. solution of common salt for five minutes, and then wash thoroughly in six changes of water at intervals of five minutes.

The purpose of this washing is to remove all acids from the film and paper, and it may be to some extent curtailed by making the salt bath alkaline with carbonate of soda. This will then neutralise any acid, and at the same time convert the soluble silver salts into chloride.

After this treatment the prints can be fixed, but the hypo solution should be fresh and not have been previously used. The prints should then be washed and again immersed in a fresh and second hypo bath so as to ensure total solution of the silver hyposulphites. Then they must be thoroughly washed, and are ready for the sulphide bath.

I find that the slower the action of this bath the better; it should take at least a quarter of an hour to reach a purple brown tone, beyond which it is impossible to proceed. Rapid toning causes the formation of a silver sulphide which is not the monosulphide, and yellow whites and half-tones and rapid fading are the result.

If actual gold and sulphide toning is required, then the proper salt to use is the aurous sulphide dissolved in ammonium sulphide, and with this an almost black image is obtained which consists of silver monosulphide plus gold. I have paper prints thus toned which are apparently as brilliant and as fresh as the day they were made.

Aurous sulphide is extremely easy to make, but it requires the use of a fume chamber, and it is prepared by passing sulphuretted hydrogen through a strong boiling solution of gold chloride, collecting and washing the precipitate and dissolving in ammonium sulphide. If some energetic dealer were to place such a solution on the market it ought to find a ready sale, for the tones given by it are excellent, and the prints certainly as permanent as any print can be, if they are properly treated.—Yours faithfully, R. E. CHESTERMAN, D.Sc.

#### ROYAL PHOTOGRAPHERS.

To the Editors.

Gentlemen,—In your list of "Royal Photographers," page 31, January 12, 1906, you have omitted to place my name. I hold a warrant from the Lord Chamberlain as "Fine Art Photographer" to His Majesty, and my name is duly entered in the "London Gazette" of January 2, page 16. I shall be obliged if you would kindly correct this in your next issue, and remain, yours faithfully, WILLIAM E. GRAY, F.R.P.S.

92, Queen's Road, Bayswater, W.

January 13, 1906.

[We regret the oversight of Mr. Gray's name in compiling the list from the numerous entries in the "Gazette."—Eds. B.J.P.]

#### A WAGES QUESTION.

To the Editors.

Gentlemen,—Various letters have appeared these last few weeks on the above question, the one of most note being that of "Comyn." I should like to say that I, like Mr. Crombie, do thoroughly understand the three-colour process, and I have even made negatives after the camera has been moved, and obtained perfect register. I also understand line-negative making by dry plate process, multiple negative making, and am thoroughly used to the photographing of all kinds of pattern work, machinery, etc., retouching, blocking-out, and use the knife on the negatives, and making the most of them for reproduction purposes; also slight knowledge of working-up the prints to obtain the proper tone value. I am also considered a very good portrait operator, understanding all printing processes. I have spent many years in professional houses. I have also had three years in process houses, but I am at present bound to accept less than Mr. Crombie's £4. I would certainly advise him to keep the berth he has

now got, for he would, like me, I am afraid, find a difficulty in getting another where his abilities would be of real value. I should very much like to obtain a berth in an engineering firm, as commercial photographer, but finding the vacancy is the real difficulty, most firms employing men who originally started as clerks, etc., and have obtained their present positions by gradually becoming expert workmen.—Yours faithfully, COMMERCIAL OPERATOR.

Birmingham, January 16, 1906.

#### THE CHROMIUM INTENSIFIER.

To the Editors.

Gentlemen,—I am afraid your criticism of No. 74 of the Photo-Miniature is misleading and inaccurate. Its reader is led to suppose, almost, that I wrote the whole number, whereas a small portion only was mine.

But your critic is a little wide of the mark to say that wherever potassium chromate was mentioned, the bichromate should have been mentioned in its place! The chromate is not an "unfortunate slip," and if your critic used it instead of the bichromate in the way I described, possibly he would get a black, and not light brown, image.—Yours, etc., T. THORNE BAKER.

16, Rutland Park Mansions, Willesden Green, N.W.,  
January 14, 1906.

[Mr. Thorne Baker's first complaint is hardly justified by reference to the review in question, for there appears to be no suggestion to the effect that he wrote the whole book. With regard to the use of potassium chromate, the suggestion that the writer meant the bichromate seemed to be warranted by the context, and also by the obvious fact (which must be known to Mr. Baker) that the use of the chromate instead of the bichromate is only a roundabout way of arriving at a solution that is of the same composition for all practical purposes. The use of chromate is very unusual, and the book gave no indication that Mr. Baker intended to describe an unfamiliar variation of an old process; on the contrary, it seemed to suggest that the chromium process described was the one previously referred to.]

Mr. Baker's theory that the chromium deposit is blackened by the developer is rather a surprising one, considering that no black chromium oxide compound is known to exist, excepting in a dehydrated state, and that a temperature of 200 deg. C. is required to produce that compound. An attempt to satisfy Mr. Baker's desire for an experimental test has led to the following result: A solution prepared with potassium chromate instead of the bichromate was used, and the brown compound produced by the action of the silver was not blackened by the action of the developer. In a gelatine film it was very little affected, and in a test tube experiment it was simply reduced to green chromic hydrate. These results are precisely the same as those obtained with the solution prepared from bichromate. The statement in the book to which exception was taken was to the effect that the developer reduces the chromium compound to a black chromic substance. The review pointed out that the substance is brown though the image is black, hence the reference in the above letter to the colour of the image is beside the mark.—Eds. B.J.P.]

#### THE INVENTOR OF THE ENAMEL PROCESS.

To the Editors.

Gentlemen,—Here are a few notes from "Process Engraving Notes and Queries" in the "Inland Printer," Chicago, for September, 1903, that give some information regarding the inventor of the enamel process for etching on copper, referred to by Mr. Dundas Todd in your issue of December 22 last. Mr. William G. Breuker, of Philadelphia, is the authority for the following:—"In the 'Photographic News' for November, 1881, is an article on M. Garnier's new method of photo-engraving. The peculiarity about it was the coating of a plate of copper, with a solution of sugar, bichromate and water, which coating, after being printed under a negative and developed, was burned in, as is done at the present time. About the year 1885, Charles E. Purton, an etcher employed by Crosscup and West, in Philadelphia, who had been using the albumen-ink method for making half-tone etchings from F. E. Ives' process negatives, modified the foregoing Garnier enamel method and used it successfully in producing relief copper half-tone etchings. To Mr. Purton belongs the credit of being the first to produce relief copper half-tone etchings. The end of the year 1888 Mr. Purton and two other employees left the firm to start the Electro Tint Engraving Co. Mr. Purton, having kept his enamel formula secret, left the old firm in a predicament. Their customers demanded etched copper plates, which, being turned out by the albu-

men-ink method, did not satisfy them. They wanted an enamel surface on the copper. Mr. Fowler, with Crosscup and West, solved the problem by using gum arabic, albumen, etc., sensitized with a bichromate as a sensitive coating, which, after development with water, was changed into an acid resisting surface by a high degree of heat, the same as described in the Garnier method. Gum arabic was used for a couple of years, when some experimenter found that liquid fish glue answered the purpose better than gum arabic. The first publication of a formula relating to the wet enamel process which I can find is in the 'Artist Printer,' beginning of 1892, in an article on the fish glue enamel method by W. H. Hyslop.—I remain, sincerely yours,

S. H. HORGAN,

Editor "Process Engraving Notes and Queries" in  
the "Inland Printer."

213, Franklin Street, Bloomfield, N.J., U.S.A.,  
January 2, 1906.

#### FREE SITTINGS To the Editors.

Gentlemen,—With the advent of the New Year would not half-an-hour in serious thought be well spent to face fair and square the unsatisfactory business of "free sittings" ("complimentary" sounds better and is more useful as a bait). Can a business of any class be built up and maintained by that unsavoury material?

Indeed, it is an open question whether any high-class right-thinking person would take it as a compliment to receive an invitation from a firm which systematically sends them out broadcast to all and sundry. Would they not be likely to look at the motive that prompted such an action, from a true business point of view? Some people have such an aggravating way of being able to see "just a little further than their nose."

"Why should Mr. So-and-So invite me to come to his studio for a "complimentary sitting" (as he terms it), pay heavy rent, and run a staff of assistants for the pleasurable gratification of taking my photograph whether I wish my vanity perpetuated or not?"

Such practices, I fear, have a tendency to lower the standard of a high-class establishment. To such one of two things must be plain. Either the business must be in a very bad way or be conducted upon lines of a questionable character. On the other hand, there are many who out of pure curiosity readily accept the "bait" and "do" the round of these "free" studios. When this has been accomplished the whole series of proofs are collected and classified, and for obvious reasons the majority are condemned. One set probably may be selected, and a small order given to the photographer "just to compensate him for all his trouble." The others have to write theirs off with other losses incidental to business speculations of that class.

I grant you there are exceptions. A nicely-worded invitation to a person likely to do one some good may with advantage be sent. Again, there are times when opportunities present themselves to suggest a complimentary sitting, but to send out offers broadcast, I say again, is not calculated to improve the tone of any really good class business.

What is the sequel to all this? Work hard to build up your business in a legitimate way. Give your sitters only that which is artistic and commendable, something better than your neighbour, and you will soon find your clients take this as the greatest compliment.—Yours faithfully,

CHAS. WYRALL.

Broad Lane, Hampton, Middlesex. January 13, 1906.

[We entirely endorse our correspondent's views. The cheapening of photography in the public estimation is a most fatal element in professional photography, and its growth is very greatly the result of the system of "free sittings." We refer to a case in point elsewhere.—Eds., B.J.P.]

#### A GOOD WORD FOR PRINTERS. To the Editors.

Gentlemen,—In reviewing a circular booklet in this week's JOURNAL, which I recognised as familiar, one important particular is omitted, or perhaps you did not know that the general get-up and artistic appearance was due to the printers, Messrs. Walter Pearce and Co., who not only printed well, but very promptly.

While writing may I congratulate you on the very interesting and up-to-date matter to be found in the JOURNAL? Not too much of the deeply scientific certainly makes a more useful and interesting paper to the average professional.—I am, yours truly,

A MIDLAND PROFESSIONAL.

January 13, 1906.

## Answers to Correspondents.

\**\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\**\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

THE HALF-TONE PROCESS.—Will you please tell me how half-tone blocks and zinc type are made, and if there is a book on the subject?—J. H. KINSMAN,

We cannot tell you within the limits of this column. Better get a good book on the subject, such as "The Half-Tone Process," by Verfassor (Iliffe and Sons, 6s.).

STORING NEGATIVES.—1. What do you consider the best ways of arranging negatives, so that on receiving re-orders you can easily find any particular one. 2. Is the system of numbering the negative and writing the corresponding number on the back of mounts a reliable one?—OVERDENSE.

1. The most convenient method is to store the negatives in some form of file in which they rest vertically. There are a number of files of this kind on the market, but you cannot do better than obtain particulars of the so-called "Negasy's" system from Messrs. Houghtons, Limited, who have adapted vertical filing specially to photographers' requirements. 2. We consider the system as satisfactory as any, if an index is kept posted, in which the numbers corresponding to any given date or period are entered.

ARTIFICIAL LIGHT, "En Avant," and others. In our next.

COPYING A MINIATURE.—I have been asked by a friend to copy an old miniature which has a convex glass in front. He desires that the glass may not be removed for certain reasons, not necessary to mention. Is it possible to get rid of the reflections from the glass by putting the miniature in a sort of tunnel of tissue paper or otherwise? If so, what is the best form of tunnel to use? Any hints in your correspondence columns would be much appreciated.—KATHON.

The best result would undoubtedly be got if the glass were removed. Failing that, the lighting of the picture must be dodged. We would suggest that it be placed in front of a window, with the camera outside. Then, if any reflections are seen, the top light should be screened off with tissue paper till they are avoided. As a miniature is but a small thing, there is no reason why the reflections should not be avoided with a little dodging.

F. N. H.—As regards the lens, it is yours, as you paid for it; and you need not give it up. The one who now claims it has his remedy against the one to whom he supplied it. If you can prove wilful misrepresentation with regard to the business you may have cause of action. Your best way will be to consult a solicitor and put all the facts before him, and act on his advice.

GLAZING PRINTS.—I should be much obliged if you could tell me whether there is any practical way of glazing cards, such as the enclosed, so as to resemble a P.O.P. card, or a glossy bromide. I have seen them done in this way, but as there is no gelatine surface, I do not see how it can be done except by coating the face of the card with some varnish or other solution which would dry with a high polish.—M. DARTON.

The prints may be glazed with an aqueous solution of lac in the same way as collotypes are glazed. Boil together (till the lac is dissolved) bleached shellac, five parts; borax, one part; water, twenty parts. Filter and dilute with warm water according to the gloss desired. Float the prints on this and hang up to dry.

ELECTRIC LIGHT IN STUDIO.—I should be pleased if you would enlighten me on the following subject. I am just starting to use electric light in the studio for photographing; it is the Aristo arc lamp, 10,000 candle power. I should be pleased if you could inform me as to the best diffuser to use, and what colour. If you recommend calico, is there any solution to treat it with, so as to guard against it catching fire, as there is a great heat from the lamp.—ELECTRIC LIGHT.

If the lamp is mounted in the usual way, that is, in umbrella-shape reflector, with the small reflector to screen the arc,—no diffuser is required. The light then comes from what may be termed a white cloud. Calico or muslin may be rendered unflammable by soaking it in a strong solution of tungstate of soda. See under "Ex Cathedra."

LIVERPOOL.—You can take action against the second firm, but not against those who copied it before registration. The reference was a printer's error: it should read, "you would not be able."

PUZZLED PROFESSIONAL.—The prints look as though the paper had been fogged by previous exposure to light. If the developer is rightly compounded, this seems the only cause deducible from the facts as stated.

PUBLISHING A PICTURE.—Will you kindly inform me, through the correspondents' column, as to the best course to take to get a photogravure reproduction of a valued painting on to the market. The picture is a "Head of Christ," by Solomon, a beautifully-executed work. How would it be to submit it to a publisher who would publish and sell on commission? If so, could you give me the names of one or two houses open to this business?—F. MILLS.

We should say that the best way would be to submit proofs of your photogravure to some of the fine-art publishers, the addresses of whom you will find in the "London Post Office Directory." Unless the photogravure is of the highest class and of a good size, it will be of no use for you to submit the photogravure to any of the first-class publishers, such as Agnews, Graves, and the like, as they would not be at all likely to take it up.

PLOUGHMAN.—We should advise you to use your stigmatic, as this would have a flatter field than your other lenses, and would, therefore, work at a larger aperture. It would be necessary to use, of course, the 15 by 12 camera, and you could place the bromide paper in the dark slides, using, if necessary, to keep it flat a sheet of plate glass in front, and making allowance for this in focussing. As regards the illumination, you would probably find that a couple of lamps, one on each side of the negative, with a white reflector, bent into a curve, would give you more even illumination than the direct rays from a lamp, and, provided you obtained two fairly powerful lamps, the exposure would not be excessive. We shall be glad to help you further if we can.

RODINAL.—Will you kindly tell me of a preservative which can

be added to rodinal developer which will not affect its developing power. I want to stock it in a 15oz. bottle, but find it turns a dark crimson colour in about three days after the bottle is opened. Does it keep better in powder form, and how long?—ASSISTANT.

If the rodinal is made up in a concentrated form it will keep well; it is only when dilute that it changes colour rapidly, but this does not impair its developing powers much. Still, the addition of 2 oz. of sodium sulphite to the 15 oz. would help considerably. It certainly keeps better in the dry form, and if in a well-stoppered bottle will keep for months.

BURNISHING.—1. Yes. 2. Castile soap in powder 1 oz., water 2½oz., methylated spirit 17½oz., allow to stand for a week, and then filter. 3. Till they are surface dry. 4. As hot as the hand can comfortably bear. 5. Yes; practically the greatest pressure the better. 6. No, there is no such work. 7. Any mount-seller could supply the cardboard; white Bristol boards is what you want.

INTERESTED SUBSCRIBER.—We certainly should not say your negatives were over, but rather under, exposed. You state that you use  $f/11$  stop. This is an impossibility, because the single combination of your lens only works at  $f/12.5$ . You have probably ignored the fact that in using the single combination you are halving the aperture, and therefore the exposure should be increased fourfold! Some of your pinholes look like mechanical scratches on the film. Why do you not use the plates you have always been accustomed to? The negative you send speaks well for the keeping power of the plates, as they have been through a good deal. The only fault with your portrait is that the lighting is too general, and rather too much in front, and you have in consequence a want of roundness which you would get if you had a shadow side. If you like to send up sketch plan of your studio, and mark the north and indicate the curtains you are using, and a print, we may be able to help you further. In any case, you have carried development too far, and this negative would tend to give you a hard print.

The "St. Louis and Canadian Photographer" announces in its current issue that it has passed out of the hands of Mrs. Fitzgibbon-Clark, who feelingly bids farewell to its readers. The incoming editor is announced as Mr. Tony O. Babb, of whose catholicity, if we may use the term, such instances are afforded as his inclusion of "Household Hints." We are interested to note that sugar, added to the fat for basting meat gives a richer flavour, particularly to veal. Perhaps we cannot take the Canadian outlook, but we are unable to see the precise relevance in a photographic journal of the announcement that "a big fat woman always claims that her bones are small." There is the opportunity for Mr. Babb to edit his paper, we think.

The first annual exhibition of the Worthing Camera Club will be held at Bedford Hall, Worthing, on March 27 and 28. There will be the usual open and members' classes. Entry forms may be had shortly from the secretary, Mr. E. F. H. Crouch, 11, South Street, Worthing.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

### SUMMARY.

A demonstration of cinematography in colours is to be given in London to-day (Friday). (P. 69.)

The unconventional in portraiture is recommended to the attention of professional photographers as an opportunity of new business. (P. 63.)

The exhibition of colour photography at THE BRITISH JOURNAL OF PHOTOGRAPHY has attracted much attention from the Press and public. A lengthy review of the exhibits appears on P. 64.

A variant of the gum process, possessing the advantage of visible printing, was demonstrated before the Wolverhampton Society by E. H. Griffin. (P. 67.)

The prospectus of the forthcoming international exhibition of photography in Paris has been published. (P. 68.)

A gelatine plate or film in which the developer is contained on the back and dissolves on the exposed plate being placed in water has been patented. (P. 70.)

A film package for the exposure and daylight-changing of flexible film, and a developing box, are among other patents of the week. (P. 70.)

The "Ideal" flash-lamp and the "Boardman" electric arc lamps (artificial lights for portraiture) were demonstrated at the R.P.S. on Tuesday. (P. 74.)

An *exposé* of the free enlargement dodge is being actively prosecuted by the Hull branch of the P.P.A. with the assistance of the Hull Press. (P. 75.)

An outline of process reproduction methods was given before the R. Helen's Society by Mr. S. A. Buckley in the course of a lecture on "Commercial Photography." (P. 76.)

Development by the Watkins time system. The report of a demonstration by Mr. P. Whitehouse before the Handsworth Society reported on P. 76.

### EX CATHEDRA.

#### Election Results in the Lantern.

During the last week or so the optical lantern has been largely used for the purpose of showing election results, and from sundry sources we learn that great difficulties have been met with owing to the enormous heat given out by the powerful arc lamps used. We have heard of several cases in which the slides have been destroyed almost as soon as they were dropped into the carrier, and of at least one case in which the carrier itself dropped into a heap of charcoal. It is needless to add that not a few condensers also came to grief. It is evident that for work of this sort the slides must be specially prepared to resist heat, while the operator must be specially skilled in the use of the arc lamp, and probably not a few "experienced" operators were surprised to find how little they really knew about it when they began to manipulate lamps of the most powerful type. We hear that in at least one instance typewritten lantern slides, prepared by a powder process, were used. It appears that the matter was typed in an adhesive ink on to sheet gelatine, and then dusted over. Presumably the gelatine was then bound up between glass plates to form a slide. The effect would no doubt be much better than that of an inscription scraped out on varnish, but we have not heard how the typewritten slides resisted the heat, though it appears that some varnished slides came to grief.

#### A Word to Assistants.

The correspondence in our columns on "getting on" raises some interesting points. It is curious, for instance, to note how the chronicle of a man's success immediately fills others with the desire to do the same kind of work. Thus a correspondent's mouth waters, and he obviously wonders how he can get such a situation as "Comyn" occupies. The point of "Comyn's" letter was that every worker should improve himself and increase his knowledge, even at some sacrifice, and that ultimately the information acquired will possess a value, and a cash value. We would suggest to workers in any branch of photography that the best method of getting on is to study the special conditions under which they are working, and the probable trend of things. This should render them efficient now and prepared for future developments. We should be sorry to write in such a way as to discourage the older and the married assistant from attempting to improve both himself and his position. He may and must do so, but there can be no doubt that it is for the man under 25 or 27 that the greatest opportunities exist. The young assistant may easily earn enough in 8 or 9 months to keep him for a year, thus enabling him to devote 3 or 4 months to the study of some further branch of his work. A rolling stone is said to gather no moss, yet we think that an operator who got a knowledge of French or German and then went into a Continental studio for a

year would be worth more than an equally capable man without his experience. America is so accessible that a knowledge of transatlantic methods might readily be added to other qualifications. The youth who finds that 25s. or 30s. a week will provide him with the ordinary comforts of life, and who makes no effort to get more by improving himself, will almost certainly find himself later on gradually squeezed downwards through the advent in the labour market of those better equipped than himself.

### Carbon-Process Discoveries.

At a recent meeting of one of the provincial societies an alleged new method of sensitising carbon tissue was described by Mr. J. W. Osborne, namely, the substitution of part of the water, used in making the solution of bichromate, by methylated spirit, and the application of the solution to the surface of the tissue with a brush. Most of the older carbon workers will very naturally wonder wherein lies the novelty of the method. Sensitising the tissue on the surface only was frequently advocated in the very earliest days of the carbon process, and the addition of a large proportion of alcohol to the sensitising solution has been very general in hot weather when there is a fear of the gelatinous coating partially dissolving and running off the paper. The immersion of the tissue, after sensitising, to abstract some of the water when it is desired to dry it quickly, particularly in hot weather, is very common. In our issue for December 22 last we had some comments on a patent for improvements in sensitising carbon tissue in such a way that it would dry rapidly. The improvement consisted in the addition of a large proportion of a volatile liquid to the aqueous solution of the bichromate: the solution being swabbed on with a tuft of cotton wool, or a brush. We then referred to this system of sensitising as being a very ancient one; it is therefore curious to see it so soon advanced as new. One of our contemporaries, in an editorial note on Mr. Osborne's paper, says: "Hitherto the best of our knowledge, this method has not been applied to the sensitising of carbon tissue, and thus forms both an interesting and valuable contribution to our knowledge and practice of the carbon process." Our contemporary goes on to suggest an improvement of Mr. Osborne's formula, by the substitution of bichromate of ammonium for bichromate of potash, and the addition of a certain proportion of carbonate of soda. Why the carbonate of soda is recommended is a little difficult to conceive, seeing that its addition converts an equivalent of the bichromate into the neutral chromate which gives a slower printing tissue. We may recall the classical experiments of Eder of some thirty years ago, in which it was shown that a solution of bichromate of ammonia would bear a larger addition of spirit without causing precipitation than would one of the potassium salt. But, as we said in the issue of December 22, if a comparatively large proportion of ammonia be added to a solution of bichromate of potash a very considerable quantity of spirit may be added without precipitation—even quite double the quantity of spirit to water may be employed. The great excess of ammonia does no harm at all, as it escapes as the tissue dries.

### The Election and Candidates' Portraits.

Probably, at no previous election has photography been so much in evidence as at the one which is practically over. It is doubtful if any voter throughout the kingdom has not received portraits of the local candidates. A friend has just remarked to us that photographers must have had a good time of it of late, seeing the use that has been made of portraits. Yet have they profited so much by it as they might have done? All the portraits of candidates that have come under our notice

have been printed from process blocks, and the photographers' names have not been mentioned on them. Before the advent of the process block portraits were used, though they were not thrown about broadcast, as at present. Then local photographers used to get good orders for prints, amounting to a good round sum. Now the candidate obtains a portrait of himself, it is then handed over to the printer of his addresses, who gets a block made, and there is an end of the matter so far as the photographer is concerned. Many photographers might, no doubt, have obtained the orders for the blocks, and also those for the circulars which they illustrated. Had they been sufficiently enterprising, they would have done a lucrative bit of business, for as a rule the printer's bill is not closely criticised at election times when the work is done by a local man. Moreover, he would see that he obtained some advertisement from the mention of his name, and that is a matter which he should have looked to in any case. Yet on not a single card that we have seen has there appeared an acknowledgment of the maker of the photograph.

### Progress in Colour Photography.

The exhibition which is now open at these offices may be said to represent the present state of colour photography, although it may not signalize any notable advance in current practice as it is known to those who have kept in touch with processes. Nevertheless, the examples of the bleach-out process of producing colours at one printing on the Szecepanik tissue as well as some specimens of one-exposure one-negative processes, should interest many who desire to see the practice of colour photography move towards a place in common photographic technique. We may also remind those who may not have kept in touch with what is imminent in photochromy that the next claimant for consideration is probably the Lumière starch-grain process by which a complete colour photograph of a scene or object is obtained at a single exposure on a single plate and in an ordinary camera. It is known that Messrs. Lumière have put down a special plant to manufacture the sensitive plates, and we shall probably not have to wait long before they will be ready to announce that the technical difficulties in the production of the plates have been completely overcome. An article describing the impression of a visit to the Lumière factory will appear in a forthcoming issue by M. Vidal, whom we have also persuaded to report on the recent process of M. Lippmann, which gives reasonable hope for the belief that by an application of the interference method copies may be made in the complementary colours from a coloured original, just as positive prints are taken from an ordinary negative at one printing. Such a system would be a necessity as soon as the Lumière process is available, and though M. Lippmann takes a very modest view of his experimental results, he has granted M. Vidal permission to communicate some notes in regard to them to readers of the "British Journal."

### Photographic Evidence.

In a law-suit in the High Courts, King's Bench Division, on Friday last, a special jury awarded a lady £500 as damages for an injured nose. From the evidence it seems that the lady was walking in the grounds of the Burlington Hotel, Dover, when she fell into an unprotected hole and was injured. Her nose was broken, and what was previously a handsome feature was permanently disfigured. In the evidence a photograph, taken before the accident, was produced to show that the lady was originally a very handsome woman. In the cross-examination of the plaintiff some questions were asked by counsel about the photographer, at Monte Carlo, who took the portrait, and whether he was not a very successful

artist. We think the fair plaintiff may congratulate herself on the reception accorded to this photographic evidence of the loss of her good looks, for it might have been shown that the retoucher's art enters so largely into the modern photograph that every woman is made at least fairly good-looking, if not really handsome. The nose, also, is the special care of the retoucher, and one rarely sees an ugly one in a lady's portrait. In this case, however, there was no question that the lady once possessed a very handsome nose—there were witnesses to testify to the fact—and hence the heavy damages. Yet photographs cannot invariably be taken as evidences of beauty, as witness many of the published portraits of actresses, some of which really bear very little likeness to the originals as seen in daily life.

#### **Objectionable Postcards.**

At the Thames Police-court, on Saturday last a shopkeeper was summoned for exhibiting in his window, and selling, improper postcards, which the magistrate characterised as filthy and vulgar in the extreme. The defendant was mulcted in a very substantial penalty and costs. It seems regrettable that the police authorities do not find out the producers of these indecent and vulgar things, and take proceedings against them for there is no question that some of the subjects exhibited and sold tend to bring the picture postcard, which is at present an important industry, into disrepute, as did similar objectionable pictures the stereoscope many years ago. It may not be generally known that any indecent print or photograph, if sent through the post, may be refused, or detained if detected in transit. The sender of it is liable to prosecution.

#### **UNCONVENTIONAL PORTRAITURE.**

ONE of the most hopeful signs of present-day photography is its great emancipation from absolute hide-bound traditions. Everyone knows the old joke of the sixties about a vase, a curtain, a table, and a pedestal as the inevitable and universal accessories. In those days the favourite pose for a man was a standing one, the legs crossed, and one elbow resting on the aforesaid pedestal. The victim was often provided with a "high hat," much more chimney-pot in shape than the present fashion, and this rested either on his head or in an inverted position on the pedestal. Ladies usually sat in a chair, the chair hidden by a mass of widespread skirts, and they either gazed placidly at the camera, or turned over the leaves of an album. As for the children, poor little mortals, they either stood on the chair clinging to its back or leant against it. We are apt to laugh at the old portraiture, but really we have advanced but slowly, and there are many men still in business who have got very little further than their predecessors of forty years ago, and in the actual matter of technique their work is worse. The fact is we have had too little individuality in photography; it has been too much of a trade and too little of an art. Photography really comes among the arts rather than among the trades, and no man can be successful at it unless he has that first essential to all artistic work, an enthusiasm in his profession. It has often been said that the influx of the amateur has benefited the profession artistically; people are apt to deal in superlatives, and people who say this exaggerate. There is no doubt that an amateur influence has been felt, as all influences must be felt, for good or for ill, but the great advance has been made by a conservative progression among photographers themselves. It is the men who get away from the conventional work, and at the same time keep to good photography and do their best on the art side, who leaven the whole mass of the profession, and more individual workers should be welcomed for the

general good they do. Even the man who perpetrates the most outré of impressionism is useful in stirring good photographers to exercise their ideas. Nothing is more essential to professional work than a well-appointed and well-lighted studio, and yet the usual sky-light, though a necessary, is not an unmitigated blessing. A man knows what results will be obtained by altering certain blinds, or placing certain reflectors, and he works in a groove with these "tools of trade," and would be lost if he were without them. The result has been that he has divided his sitters more or less into classes; one will make a good profile, another a good full length, a third a Rembrandt, and in striving after these classes he has omitted the essential of character; instead of adapting his means to the sitter's individuality, he has moulded the sitter to his stereotyped means of expression. It is not that the possibilities of studio work are limited to these methods, but that the results being easily obtained photographers have drifted into them. The late Adam Salomans, who was an old-fashioned worker but thoroughly sound and progressive, used to keep his work up to par by practising different lightings and poses for a fixed time every day; if anyone could be said to know the limit of possibilities it would be a veteran worker like Salomans, but he frankly felt that practice and study were necessary through life.

We were lately looking at some very effective work by a provincial photographer whom we had known as a successful photographer of children. On visiting his reception room we found that child pictures were not more in evidence than in any other well-appointed room, but we saw some very pretty and effective outdoor pictures, mostly of ladies. There was no incongruity about them; there was not a single outdoor lady in evening dress, and most of them were in walking costumes. He had had the idea of taking some of his sitters in his rather pleasant little garden, and commenced by asking suitable persons, after they had sat for the usual studio exposures, if they would allow him to try one or two negatives in the garden. The results were very successful. The top light was cut off by a shady tree, or in sunny weather sometimes by a parasol carried by the lady. He found that his sitters usually chose from among their proofs some of the outdoor work; they were just as pleased as ever with the retouched head and shoulders, with the delicate studio lighting, but they also liked the outdoor work, much of which did not even require the touch of a spotting brush, and the result was increased business for the photographer. Some successful amateur photographers, and by the word "successful" we mean men who have done sane commendable work, cornered by the fact that they have no top light studio, have developed methods of working in ordinary rooms. The old theory is that a studio window is necessary in order to get a sufficiency of light; the amateur usually begins by cutting off a large portion of his light, and using a concentrated light from one window only, and by this means he has obtained pictures which cannot be called better perhaps, but which are different from the usual studio work. Being divorced from the possibility of giving conventional sittings, he has turned his attempts towards portraying the characters of his sitters, and in this direction he has at times been very successful.

We do not advise that photographers should discard studio lighting, and turn to dining-room windows and other makeshifts; the studio light has wider possibilities than anything that the amateurs practise with, but a study of such light is interesting and helpful, and a photographer who practises unconventional portraiture of various styles will not only enlarge his horizon and improve his work, but may find that he develops a specialty which may become a paying side line.

## AN EXHIBITION OF COLOUR PHOTOGRAPHY.

THE first exhibition of examples of colour photography held in England was opened at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY on Friday last, January 19, and will remain open until March 3. The exhibition may be visited without charge between the hours of 10.30 and 4.30 (Saturdays, 10.30 to 12.30). The collection includes some 150 examples of colour photography in the form of prints and transparencies, with a number which may be described as "colour effects in photographs." The great majority of the exhibits are by the three-colour process, that is to say, the negatives are obtained in the usual way through three screens. The chief interest of the exhibition to the visitor lies in the examination of the results of printing from the three negatives by the different processes now available for the purpose. The catalogue which is presented to each visitor—it is not sent in response to application by post—identifies each exhibit with its method of production as far as the information supplied by the contributors renders possible, and it is therefore hoped that a visit to the collection will deeply interest those who make a study of the comparative value of the various processes as well as the less critically minded who may wish to see to what stage colour photography has now arrived.

At the time of writing, the small gallery in which the collection is arranged has been open only for four days, but some two hundred persons have placed their names in the visitors' book, and expressed themselves pleased to have accepted the invitation addressed to them personally, through our columns, or in the daily Press. Among those who have thus approved by their support the action taken by THE BRITISH JOURNAL OF PHOTOGRAPHY in organising the exhibition are: Mr. Chas. Sawyer, Mr. T. R. Dallmeyer, Mr. Geo. Scamell, Dr. O. Rosenhain, Mr. A. L. Burdick, Lieut.-Colonel Simpson, Mrs. F. W. H. Meyers, Mr. Alvin Langdon Coburn, Mr. George Bernard Shaw, Mr. C. J. Drac, Mr. T. S. Bruce, Mr. C. Welborne Piper, Mr. T. K. Grant, Mr. Henry Stevens, Mr. A. Horsley Hinton, Mr. J. D. Robertson, Mr. H. O. Klein, Mr. Austin Edwards, Mr. Chapman Jones.

### THE LONDON MORNING AND EVENING PRESS ON THE EXHIBITION.

The temptation to sensationalism which seems irresistible to lay journalists when they write of colour photography has been responsible for some of the statements which have been made in the Press in reference to the exhibition. The technics of three-colour and other processes is a theme which the most graphic writer must find beyond the powers of his pen, and thus the notices which have appeared in the daily Press have mostly been confined to statements of opinions and preferences. A few extracts are quoted here.

"The exhibition includes numerous interesting examples of the various applications of the three-colour process."—"Daily News."

"It will be seen that a colour-photograph never represents actual truth. It is a compromise between the operator's perception of the truth and his taste in colour tones. The visitor to the Wellington Street gallery can judge for himself which of these arbitrations of tint he prefers; a single spectator can only affirm an individual pre-

### A REVIEW OF THE EXHIBITION—BY E. J. WALL, F.R.P.S.

The exhibition of colour photography which is now open at the offices of the B.J. is, I believe, the first of its kind which has been arranged in England, and is of extreme interest to every professional and amateur, because the examples shown are only by those processes which can be used without any special machines or apparatus—that is, are in no way photo-mechanical—and are therefore applicable to the production of portraits by professionals and of ordinary or extraordinary subjects by amateurs.

The effect which a photograph in colours produces on an observer cannot by any possible means be gauged. It is a personal effect entirely, and there seems to be absolutely no law or rule by which one can estimate how such prints will be received. When monochrome prints are examined, whilst there may be diversity of opinion as regards the composition and technical rendering of a subject, there will be found a decided majority one way or the other; but this I have never met with when colour prints are in question. The following notes must therefore be considered purely as my impressions

The visitors have not been drawn from London only, for the entries include names from Birmingham, Ramsgate, Southport, Folkestone, Portsmouth, Bristol, Wellington, and Kimberley (South Africa), suggesting that the exhibition has already attracted widespread interest in photographic circles in all parts of the country, and that just in the present the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY are a rendezvous where one is most likely to meet with those interested in the latest developments in that most fascinating of all branches of photography, the reproduction of scenes and objects in their natural colours.

We may add a word of excuse in reply to several letters we have received from those who tell us they would have gladly contributed to the collection had they been notified of its projection. Not unnaturally they blame us for not publicly inviting exhibits. We would say in extenuation that the wall space at our disposal is not unlimited, and we were anxious not to ask for contributions which we could not hang. Moreover, we believed that we were in touch with all the people likely to have examples for exhibition. Lastly, as the opening of an exhibition of this kind was an experiment which we were making for the first time—for the first time in photographic journalism, in fact—we were reluctant to make any public announcement until we were satisfied that the response would be such as to justify our announcing an exhibition fairly representative of the present position and practice of colour photography. Events, we are glad to say, have fully confirmed our desires, and we must thank those who have been good enough to entrust their works to us in the public interest. Nevertheless, some available space still remains, and we therefore ask all workers in colour photography to note that we will add any *prints* which we may approve to the exhibition and indicate its author and process on the frame pending the issue of a second edition of the catalogue. Several such exhibits have already been added, but we beg particularly to say that this invitation applies only to prints: we have no further space for transparencies of exhibits requiring to be illuminated by transmitted light.

ference for the 'Autumn Landscapes' (57, 58) of Dr. Julius Moeller, as being nearest to his perception of the true and the admirable."—"Daily Graphic."

"The specimens on show in Wellington Street have all the merits and demerits of their class. What the exhibition does is to permit those interested in the subject to compare the achievements of different processes."—"Westminster Gazette."

"It is well worth seeing."—"Sunday Sun."

"The flower and fruit studies are remarkably fine."—"Daily Express."

"Miss S. A. Acland, F.R.P.S., working with the Sanger-Shepherd process, has produced (as a transparency) a notable portrait of her brother, Admiral Acland, and her scenes of Gibraltar also deserve attention."—"Morning Advertiser."

formed by a careful examination of the exhibits, modified, if you like, by personal experience.

The exhibits may practically be divided into two classes. The first relies on the three-colour principle, in which it is necessary by means of colour filters to split up the subject into the three constituent negatives, representing the red, the green, and blue-violet luminosities, from which negatives prints are made in yellow, red and blue.

#### The Principle of Three-Colour Printing.

This choice of printing colours frequently forms a stumbling-block to beginners, because they do not grasp why the negative, taken through a green screen, for instance, should be printed in red, but it becomes very easy to understand when the action of the filters is understood. For instance, putting the matter very roughly, the red screen cuts out all the blue, the green screen cuts out all the red, and the violet screen cuts out all the yellow. Therefore, in each case, the colour which is cut out does not act on the plate, and gives us more or less

bare glass. Now, every photographer knows that it is the shadows, or the bare glass parts of a negative, which print, and, therefore, if we expose any paper under the negative taken through the green screen, the print that we obtain represents all the red that was in the subject. By exactly the same reasoning it will be seen that a print from the negative taken through the violet screen will represent all the yellow in the subject, and that from the red screen negative represents all the blue. Therefore we must use red, yellow and blue as the printing colours under the green, violet and red screen negatives respectively.

The second class comprises prints which show "effects of colour," and for which one negative only is used. This I shall refer to later on when dealing with specific exhibits of this kind.

### Three-Colour Carbon Prints on Stripping Films.

The first six exhibits are produced by means of superimposed carbon prints produced by the stripping pigment tissue made by the Rotary Photographic Company. This consists of yellow, red and blue tissues, coated on extremely thin celluloid, which is placed in contact with the film of the negative, thus doing away with the necessity of double transfer, which would considerably complicate the accurate superposition of the constituent prints. The exhibits are very satisfactory, and show brilliancy without crudity of colouring, though Turner's "Temeraire" (No. 6) is a little dull-looking. No. 9, "Tulips," by W. E. Brewerton, also by the carbon process, is a signal success, and when compared with his other two exhibits, Nos. 7 and 8, strikes me particularly from the great transparency of the print. All Mr. Brewerton's exhibits are taken through the Sanger-Shepherd screens. No. 10 is also a carbon print, by M. Vidal, and is obviously a copy of a painting, and shows a brilliancy of colour, which is remarkable. Whilst in the absence of the original one cannot speak as to its correctness, it so obviously belongs to the French school as to be so. It is noticeable, too, for the great range of colouring shown.

### The Sanger-Shepherd Process on Paper.

Of all the portraits shown, I, personally, should give the palm to No. 11, which is by the Sanger-Shepherd process on paper. There is a softness of colouring and texture which is really very remarkable, partaking rather of the character of an oil-painting than a colour photograph. Presumably this is prepared by the imbibition process in which a gelatine relief is obtained, then stained with a suitable dye, squeezed into contact with a gelatinised paper, when the dye is absorbed by the damp gelatine from the relief, and by superposition the coloured print is obtained. It is obvious that paper need not necessarily be the support for the finished print, but that ivory celluloid, opal glass or fabric may be successfully used. Another modification of this process, which has already been outlined by the inventor is the use of a ferro-prussiate base for the blue impression, and this may prevent some advantage.

Since the exhibition was opened and the above notes written, another portrait by the Rotary Company's superimposed carbon tissues has been hung, and which, I think, divides the premier honour with No. 11. These two exhibits should be most carefully examined by all professional photographers, for they prove the possibility of obtaining life-like and artistic portraits in colours.

It may, of course, be advanced that the necessary exposures are very long. So they have been in the past, but I am now in possession of a set of colour filters with which the necessary exposure for the violet, green, and red are respectively 1, 2, 2, using a pinachrome bathed plate. Considering that the increase in exposure with the violet screen is four times it will be seen that the total increase in exposure is only 20 times, which makes three-colour work in the studio possible. The new screens are made by Meister Lucius and Brünig.

Nos. 12-17 are prints by Dr. B. Jumeaux' process, which, in the supplement briefly explanatory of the processes, is stated to be the formation of a blue bromide print by toning, obviously the formation of ferro-prussiate and the superposition thereon of red and blue stained films. There is to me in these a preponderance of red which is extremely irritating and obviously untrue. We are further told that the portrait of the King is "a two-colour result with red and yellow images." In the face of this statement it is a little difficult to understand the bright blue ribbon of the Order of the Garter which His Majesty is shown as wearing. This is, I think, the best of this lot.

### The "Pinatype" Prints.

The next process illustrated is that of pinatype, which is also an imbibition process. Ordinary transparencies are made from the three constituent negatives, and printed on to bichromated gelatine plates. The bichromate is washed out and the images stained and successively transferred to paper. These are decidedly good, and the range of subjects shown proves very satisfactorily the capabilities of the process. It is not a difficult one, and my trials with it have been satisfactory. There is one point upon which some doubt might exist. It is as to its permanency, but in conversation with Dr. König, the discoverer of the process, at the R.P.S. exhibition last autumn, I learnt that some specimens had been exposed to full daylight for many months without showing any change. This process differs from the Sanger-Shepherd in that the latter process requires a low relief in gelatine, obtained by dissolving in warm water the unacted upon bichromated gelatine, whilst in pinatype the print-plate is merely treated with cold water, and there is no gelatine dissolved, and the unhardened gelatine absorbs the dyes.

No. 23, "Vegetables," by E. R. Grills, on matt paper, is rendered particularly interesting, because with it is shown a companion pinatype print on glazed paper, and the superiority of the latter is at once apparent.

### Three-Colour by Dr. Grün.

The next series of prints are by Dr. Grün, and are apparently all by modified processes, which are not satisfactory. Nos. 24 and 25 show a want of coincidence of the individual images, and the rendering of the colours is unsatisfactory in most of them. Assuming that the article in "Penrose's Annual," by Dr. Grün, describes the process or basis of the processes used, the following is a summary of the same:—A blue-toned base is made on a gelatinised plate or glass, then sensitised with bichromate and printed under the green screen negative, the excess of colour removed by washing, and again resensitised with bichromate and printed under the blue screen negative. Dr. Grün admits many difficulties, and says that "the method gives results occasionally uncertain, but in about 25 per cent. perfect." If, therefore, we look upon these results as experiments, they are interesting, but if they are put forward as specimens of workable processes, and the 25 per cent. of successes, they do not give me a favourable impression; and the modifications of pinatype are not so successful as the mother process. Note especially the preponderance of green in 37 and 38.

In 31 and 36 we have the same accessories to a figure, and the rendering in these two prints is totally different. Note, please, particularly the curiously shaped and curiously coloured stool and flower pot. There is here, also, a non-coincidence of the images which strikes me as being due to the use of a lens which does not give the coloured images of all the same size. Obviously, this condition is very important in colour work of all kinds, and the reason why opticians now make lenses which are perfectly corrected for three-colour work; for although the images may be on one plane, they need not necessarily be of the same size when using an uncorrected lens.

### Three-Colour Prints by Various Processes.

Four exhibits, by Captain Lascelles Davidson, are described as on dyed celluloid films uncemented. Why the films should not be cemented I cannot quite see, unless the idea be to obtain greater transparency; but there must necessarily be a loss of light, and, I think, of colour-rendering through repeated reflection.

In three-colour work there are certain parts of nearly all subjects which at once show the failings of a process or the particular exposures. These are the rendering of a shadow and a uniformly coloured plane surface. Bearing this in mind, No. 45, a portrait by Mr. Otto Pfenninger, at once shows a failing in the shadow on the blouse, where there is a red tinge, and also a green right hand. It is, however, interesting, as being from negatives made at one exposure. The curious blackish brown patch in the left-hand corner of No. 41 I take to be water, but no one could possibly be certain of that.

Nos. 46, 47 and 48, exhibited by Dr. Heseckel, of Berlin, are by Selle's stripping carbon process, and are hung in much too close proximity to the other exhibits on the same wall, as they throw the latter into the shade completely.

### Gum and Carbon.

Nos. 49 and 50 should be examined in conjunction with 57, 58 and 59,

for they are all bi-gum prints in three colours, and the conclusion I arrive at is that to appreciate this process the results must be large. Fifty-seven and 58 show somewhat too great a brilliancy in red—at least judged from the standpoint of English autumn scenes.

When one considers, however, the difficulties of this process, one must admit that they are good. As is probably well known, a film of bichromated gum with the yellow pigment is first laid on the paper, exposed under the violet-filter negative and developed; then on the print thus obtained is coated bichromated gum, holding in suspension the red pigment, and this exposed under the green-filter negative and developed; and finally, another film of gum and the blue pigment is coated on the yellow plus red print, and exposed and developed.

The fruit studies from paintings shown by the Autotype Company, which, it is stated, are by double transfer of carbon tissues, registration being obtained by a thin temporary support, which allows the image to be seen from the reverse side, are again brilliant and, so far as one can judge without the originals, satisfactory in colouring.

Nos. 60, 61 and 62, by the Lumière superimposed carbon process, will at once strike anyone by the richness and the liquidity of the colouring. It is unnecessary to say much about these, except that they are, I believe, made by the superposition of stained gelatine reliefs, originally produced on thin celluloid.

### Multi-Coloured Prints at one Printing.

We now come to the Szczepanik prints, the instructions for which were given in full in the *B.J.* for January 12. From No. 56 it will be seen that in this tissue the three fugitive films are superimposed, whereas in the process, as worked by Wörel and Dr. Neuhaus, a mixture of three fugitive dyes in one film is used. In fact, the latter states that he can see no advantage in Szczepanik's method (*"Phot. Rundschau,"* 1904, p. 96). Wörel uses primrose, victoria blue and auramine, and sensitises with anethol, the principal constituent of anised oil. Neuhaus uses methylene blue, erythrosine and auramine, and increases sensitiveness by the use of ammonia and chloral hydrate or hydrogen peroxide, and does away with the reeking anethol.

This film approaches, as nearly as would seem possible, to Wiener's ideal chromo sensitive film, and this idea was also used by Cros in 1881, his fugitive colours being carthamine, phyllocyanine and turmeric.

Some may exclaim at the gaudiness of the colours in 52-4, but when one recalls the usual brilliancy of the colours in lithophanes, which may be more generally known as "Glacier" window decorations, then this very gaudiness will be accepted as correct.

The interest in these exhibits lies, of course, in the fact that the tissue or film is practically black, and when exposed under a coloured original the dyes bleach out, except under their own colour. That is to say, under the red of the original the green and blue constituents bleach out, under a green the red and blue bleach, and under blue the green and red bleach. Intermediate colours, such as orange or purple, are, of course, formed by a partial bleaching of two and a complete bleaching of one dye. Whilst up to the present the sensitiveness of these fugitive dye films is extremely low, we may hope, though not prophesy, that here we have the future process of colour photography in which we should obtain by exposure in the camera a photograph in natural colours.

### "Colour Effects" from Ordinary Negatives.

The remainder of the prints are aptly described as "colour effects from ordinary or orthochromatic negatives." The first of these processes is the "Multico" paper of Dr. Heseckel, of Berlin. The original paper was patented by Slavik (an Hungarian, I believe), and consisted of three or four pigmented tissues coated one on the top of the other. On the top was a bright blue, then came a green or yellow, and then a red. Since then various patents have been taken out, in which the use of as many as seven distinct layers of pigment tissue is claimed. Probably some of the readers of the *B.J.* will remember a print of daffodils exhibited by Mr. Birt Acres at one of the R.P.S. exhibitions, held in the old Pall Mall gallery, and a paper read by him before the R.P.S. This must be more than ten years ago, which, so far as I am aware, never saw daylight again, and he there outlined practically the same idea.

As to the value of the process, visitors to the exhibition may, to some extent, judge by noting No. 64, in which there is a bromide print and a multico print from the same negative side by side. That this method can ever give photographs in natural colours, as was

first claimed for it, I certainly deny, and this is readily proved by the following experiment. If we copy a coloured chart containing a full range of colours from red to blue with an ordinary plate, there is no question that the blue will be the densest part of the negative, and the yellow and red the thinnest. Now, if we print from this on "Multico" tissue we shall get some approximation to correctness of colouring, because the dense blue would let but little light through, and, consequently, only the top film of the tissue would be rendered insoluble, whilst the bare glass representing the red would let the light act right through the tissue to the paper and render the red insoluble. Therefore, in developing our print, which is done by the transfer process, as in ordinary carbon work, we should have red and blue properly represented.

Now, however, let us take a panchromatic plate, and with a colour screen so damp down the blue that the red and yellow may act to some extent in accordance with visual luminosity, and we shall have an absolute reversal of the negative densities, and therefore in printing the yellow would be shown as blue and the blue as red, or some other colour.

Notwithstanding this state of things some good results can be obtained for pure landscape work. More than a year ago I had to make a series of tests of this paper, and obtained some really pleasing things, but when dealing with portraits, and cattle and sheep studies, I obtained some effects which were ludicrous in the extreme. For instance, I obtained a portrait of a small child with a pale blue face, in a deeper blue frock, with green hair, holding a brick-red kitten. The latter in life had been, and still is, black. The child has not a blue face, nor green hair. Again, a group of cattle turned out green, speckled with blue; but, as I have said, for pure landscape work some good effects can be obtained, and to anyone who can "fake" either by brush or cotton wool, or a fine jet of water, very great alterations may be obtained in results, and it is quite possible that pictorial photographers might find this a good field for experiment.

### The "Mars Star" Process.

The four exhibits of the "Mars Star" process do not strike me favourably; that may be, and probably is my fault. They are obtained by bleaching ordinary bromide prints and applying a series of colouring solutions in turn without intermediate washing. I should prefer good bromide prints.

The last two prints are portraits by Mr. J. Burgess by a secret process from ordinary negatives, on which there is admittedly and obviously some hand-work. They are either by a carbon or Woodbury-type process if one may judge from the great relief that they show. Certainly the results are much more pleasing than some of the other exhibits which have been obtained by pure photography.

### Sanger-Shepherd and Lumière Transparencies.

We now come to the transparencies, the majority of which are by the Sanger-Shepherd process, in which a silver image transparency, obtained from the red filter negative, is converted into ferro-prussiate, and then the yellow and red impressions are superimposed. In the Lumière process the blue image is obtained by using diamine blue F, the red with erythrosine J and the yellow with chrysophenine G. For producing these transparencies and the red and yellow images of the Sanger-Shepherd process, an emulsion of silver bromide, though this plays but a secondary part, is coated on thin celluloid, and after sensitising with bichromate and drying is exposed through the celluloid and the prints developed in warm water, and then the bromide is dissolved out and the little picture in relief stained up by the proper dye bath, and either superimposed on the celluloid base, or this may be stripped. As a rule the best results are obtained by cementing the films together. The fine set of Lumière stereo slides will naturally attract, as they have done before, great attention.

It is somewhat invidious to pick out those examples which are the best, but those from Sir Wm. Abney's negatives are very fine, as are also those by Miss Acland, but whether it be the added effect of stereoscopy, those by M. Victor Selb are exceptionally good. There is a good chance to see the correctness of one exhibit, namely, 80, which is a reproduction by this process of a diffraction grating spectrum, shown by Mr. Thorne Baker, for close handy is Mr. Edgar Senior's spectrum by the Lippmann process, the only exhibit of this kind, and an extremely successful one. The comparison of the two is a very good object lesson, and I think that Mr. Baker's result is far too purple in the violet, there is no pure blue, and the red is too

brown, this last being caused obviously by insufficient red sensitivity of the plate used. The variety of the subjects shown in this process proves how widely it can be applied.

Particularly should be noted Dr. Norman's slides, 95-98, which received a medal at St. Louis, and Dr. Hutchinson's butterflies, 99-103, which received the only medal for colour work at the last R.P.S. Exhibition. These are all by the Sanger-Shepherd process.

### Snap Shots in Colour.

There are two extremely interesting exhibits by Captain Lascelles Davidson, the value of which, however, is somewhat discounted because there is no indication of how they have been obtained, but they prove that it is possible to take snap-shots in colours, although the results are not perfect. It is to be hoped that he will tell us how they are done.

### The Joly Methods—Old and New.

There are also two of the now defunct Joly process, in which the negative was taken through a screen ruled with alternate lines of green, red and violet, which gave a lined negative, and from this an ordinary transparency on a lantern plate was made, and then bound up with a viewing screen, which was also ruled with transparent coloured lines. It will be doubtless remembered that this was followed by the also short-lived McDonough-Joly process.

The main defects in both these processes was, so far as my opinion goes, the coarse rulings, which were painfully apparent when magnified by projection. For some months irritatingly vague paragraphs have appeared in American journals about a wonderful improvement in this process, which has been worked out by Powrie, of Chicago. We have been told that he could rule the coloured lines as close as 1,000 to the inch. These statements obviously required modification or a greater plasticity for belief than I possess, but in "Penrose's Annual" for this year, on p. 111, Mr. Powrie describes the production of his plates. Had I not rather exceeded the ordinary limits of an article I should condense this. Now, we can understand the lay and inspired articles, and the process certainly appears to me to be feasible. All I want is a few of the negative and transparency plates to play with.

From my own experiments with the Joly process I was convinced that there were possibilities in such a process, that is to say, one exposure, one negative, and one positive; but I could always, unfortunately, see the disadvantages. Still, they naturally lead one to

think of the new Lumière mosaic process, in which coloured starch grains are spread over the plates as screens, and the emulsion coated on top. *Eheu! longe expectate.*

The description of this process is to be found in brief in the "B.J. Almanac," 1906, page 862, and promises well, for the very defect of the Joly processes is done away with, for obviously if the colour is obtained merely by the use of stained potato starch fecules, there would be no "grain" apparent to the naked eye.

Special interest will be excited by the three negatives taken on Dr. Smith's multi-colour plate. This, as is well known, has on the top a blue sensitive film, then a red sensitive, and at the bottom of all a green sensitive emulsion (see "B.J.," Sept. 15, 1905, p. 722). No resulting print is shown from these negatives.

### Butler's Pre-dyeing Method.

Mr. E. T. Butler's results are taken presumably with his one-lens camera, which is figured on p. 856 of the "B.J. Almanac," and the results are obtained by his pre-dye films, that is to say, he dyes his positive films before bichromatising and exposing. His method was propounded at length in the "Photographic Journal," June, 1905, p. 199, and appears abstracted in the "Almanac," p. 864. Mr. Butler's argument is that he finds it easier to follow the development of the image when it contains the dye than when silver bromide is used in the film. To some extent this may be true, but I have never found any difficulty in following the course of development with a pure bromide film, or one might, on the other hand, use an inert dye such as cochineal red, as suggested by Lumière. I cannot help thinking that Mr. Butler's plan considerably limits not only the choice of dyes, but also introduces unnecessary complications, for, as he himself admits, the dyes must not only have the correct absorptions, but stand the action of bichromate *plus* light, be soluble enough to wash out and yet not soluble enough to run. In any case, his results are extremely interesting, though I must confess that they do not strike me as correct in colouring.

The value of the exhibition, taking it as a whole, lies in the fact that there is here brought together in one room specimens by nearly every colour process extant, produced by those whom one must assume from their writings, etc., to be experts, or who are recognised as authorities, and one may therefore judge them according to their works, or their works from their writings. No one should miss the opportunity afforded, for every exhibit will teach some lesson.

E. J. WALL.

## THE FOXLEE GUM PROCESS.

[The following report of a demonstration before the Wolverhampton Photographic Society is from notes specially prepared by the author, Mr. E. H. Griffin. In the introductory to the demonstration, Mr. Griffin highly eulogized the gum process for its immense latitude and facility of control, and instanced, as examples of its use in the most accomplished hands, the motor-car photograph, "Speed," by

I do not think it will be necessary to consider any more advantages of "gum" over other processes, since the value of any method of photographic printing must be judged by the amount of freedom it allows us to obtain the desired result.

There is no safe edge, no transfer, no actinometer, troubles, etc., as with carbon; no extreme susceptibility to damp as compared with platinotype; no greenish or brownish blacks, or grey high-lights that we are sometimes subjected to consequent upon the vagaries of a developer, in the bromide or gaslight process; no dodging or straining of the neck as is necessary to see a glazed P.O.P. print, owing to the ordeal of the burnisher or ferrotype plate giving to its surface a polish, of which a shoeblack might be justly proud.

It is true that the range of tone is somewhat limited in the single coat, but that objection has been removed by multiple coating. This consists of obtaining a primary print from our negative and printing so as to obtain a faint image, and afterwards re-coating and printing, until we have sufficient strength and range of tone to satisfy us. But as I have had very little experience in multiple coating I can only say that this, effectually, to my mind, dispels anything that may be advanced as being a disadvantage in gum bichromate considered from a pictorial standpoint.

M. Demachy, and the "Lingering Autumn" of Mr. David Blount. He then proceeded to consider the technical advantages of the process, and from this point we may give the substance of the demonstration in practically the words of the author. Some notes on this subject by Mr. E. W. Foxlee are held over for want of space, but will appear in our next issue.—Eds., "B.J.P."]

### The Foxlee Process.

There have been several methods of working introduced since what might be termed the revival of gum-bichromate printing has taken place (I believe it is an old process originally invented by Poncey some 20 or 30 years ago). Each advocate of his particular method has claimed superiority either in simplicity of working, or some other detail, over others. I think the earlier methods were to first sensitise your paper, dry, and then apply the pigmenting mixture and finally print, or else pigment your paper, in the first instance, dry, then sensitise and print. The latest system (and the one most generally used) is that in which both pigmenting and sensitising are performed in one operation, and although this possesses the advantage of a single operation over the former methods, I think it still leaves room for some improvement.

The process I now wish to submit is one which I think should claim the attention of all gum-bichromate workers, inasmuch as it may be relied upon from a technical standpoint, having its origin in Mr. E. W. Foxlee, an eminent authority on all matters relating to photographic chemistry. It also, in certain working details, supersedes the others. The process, says Mr. Foxlee, is the outcome of some rather exhaustive

investigations he made some few years back with reference to the behaviour of bichromated gelatine and other colloid bodies when exposed to light.

### Mariotype.

The method of working is based upon what is known in the carbon process as the continuing action of light. After dealing with experiments more particularly relating to a modification in carbon printing, which was demonstrated by the late A. Marion (the founder of the well-known house in Soho Square) to the London Photographic Society (now the Royal Photographic Society) some thirty or more years ago, which was that the action of light set up in one gelatine film that had been bichromated and exposed, could be continued in another gelatine film that had not been exposed at all, Mr. Foxlee says he made investigation to see if the same action would take place in a different colloid—such as gum.

He found somewhat to his surprise that it would, and some paper was coated with gelatine, sensitised on a slightly acidified solution of bichromate of potash, dried, and printed. It was then coated with pigmented gum, also acidified, and then hung up to dry. Upon development next day it showed that the action had been transmitted from the gelatine to the pigmented gum.

The presence of free bichromate, however, introduced an element of uncertainty, so other prints were made, the bichromate washed away and dried. They were then pigmented with an acidified gum solution and again dried, and when developed yielded very good results. Mr. Foxlee then goes on to describe his method of working, of which the following is my actual experience.

### Sizing and Sensitising.

The papers I have used have been Whatman, Nitchal, ordinary cartridge and Wheeler's antique boards. I have found the latter suit my purpose best. It is a very thick rough paper, and has the advantage of cheapness, only costing 1s. 6d. per dozen sheets, size 24 x 20. Either side may be used, but the right side has a somewhat smoother surface than the other. It is necessary to size the paper with gelatine first. The proportions I use are: Gelatine, 1 oz.; water, 20 ozs., in which to render the surface harder I put chrome alum, 1 grain to the ounce. The gelatine is first swelled in cold water (which takes about 1 hour), the water is then poured off, and the correct quantity of hot water added. When the gelatine is melted, the chrome alum previously dissolved in a small quantity of water is added in a thin stream, stirring meanwhile. I then pour a small pool of the solution on the paper, and work it thoroughly into the paper by means of a flat hog hair brush, until there is a fairly even coating obtained.

When the paper is dry it is ready for sensitising. Here we can adapt the strength of our sensitising solution to the character of our negative. A strong negative will require a strong sensitiser to decrease the contrast. A weak negative will be improved by using a weak sensitiser. I have found that for general use, a strength of about 1 oz. bichromate of potash dissolved in 40 ozs. of water is a good sensitiser for average negatives.

I pin my sized paper to a drawing board (protected from splashes of bichromate by a sheet of paper interposed), and pour a small quantity of the sensitising solution in the middle of the paper and work it about with a soft camel-hair brush of two or three inches in width until the paper has received an even colour all over. It is then set aside to dry. It will dry very quickly in a warm room, and when dry is ready for printing.

### Exposure, and Pigmenting the Print.

Exposure is about the same as required for platinotype. Just sufficient for slight detail in the high-lights. The image will be a light brown upon a yellow background. I then leave the print to soak in water, which I change two or three times, until the yellow stain has entirely disappeared and nothing remains on the paper but a faint positive. It is then dried, and can be pigmented straight away or kept for weeks. This is an advantage, for we may keep our prints until we have an accumulation of them, and when we are inclined, pigment them all at once.

The formula I use for pigmenting is as follows:—

#### STOCK SOLUTION OF GUM.

Turkey gum .....	4 ozs.
Cold water .....	10 ozs
Carbolic acid .....	6 or 8 drops

The gum is dissolved by making a small bag of linen or muslin, and placing the gum in this and suspending it in the cold water, by means of attaching the bag to a small stick and placing it crosswise over a jar. It may take two days to thoroughly dissolve. When dissolved it is ready for use.

The print is again pinned to the drawing board and coated as evenly as possible by means of a stiff flat hog hair brush—to smear the paper all over in the first place, and then with another hog-hair brush with much softer bristles, and less of them, to smooth out all irregularities.

This is the formula I use for coating the paper with pigmented gum:

#### PIGMENTING SOLUTION.

Stock solution of gum.....	5 drams
Glycerine .....	1 dram
Acetic acid (glaciale).....	2 drams
Pigment .....	8 to 10 grains

The pigment I use is dry colour, and can be obtained from any oil and colourman, in all shades. When the paper is coated (which should be as thinly as possible) it is dried. I then leave the print under a quantity of books for pressure for thirty to thirty-six hours. The print is then placed in a dish of cold water for development.

### Development

This is conducted in precisely the same way as the usual method. With a correctly exposed print, and one left for thirty-six hours between pigmenting and development, I have found that all the soluble pigment has left the paper in about one hour. We may assist development by brushing very lightly with a soft, camel-hair brush, but I have found it better to develop the print mechanically first, and dry, then work upon it with brushes afterwards, as the film is considerably tougher when it has been once dried.

Mr. Foxlee states that in place of gelatine, for the initial print, other substances may be employed, such as the starches tragacanth, and flour paste. I have tried starch and flour, but found nothing to equal gelatine and alum, as this gives a good hard surface to the paper and keeps the image from sinking into the paper, and having a lifeless appearance.

## AN INTERNATIONAL EXHIBITION OF PHOTOGRAPHY IN PARIS.

A GREAT international exhibition of photography is to be held in Paris this summer at the Petit Palais, in the Champs Elysées. The exhibition is announced to open on July 16 and to close on October 10. The whole of the arrangements are in the hands of M. L. Gastine, director of our contemporary, "La Photographie Française," and commissaire-organisateur of the photographic exhibition held in Paris in 1892. The full text of the scheme of the exhibition has been sent us by M. Gastine, and from it we see that an influential committee of patronage has been formed in France, including, among a number of well-known public persons, M. René Baschet (director of *L'Illustration*), M. Casimir-Perier (ex-President of the Republic), Colonel Laussédot, Prof. Gabriel Lippman, M. Emile Roux (director of the Institute Pasteur), and M. Trouillot (Minister of Commerce and of the Postal and Telegraphs Departments).

We translate the circular of the exhibition so far as it explains the general scheme upon which it will be designed. For the full particulars of the tariff charged for space in any of the groups, and for the facilities which the management can offer in the way of light and motive power, application should be made to M. Gastine at the Petit Palais. We would, however, say that a charge is made for all exhibits except those in the groups devoted to the history of photography (No. I.), scientific applications of photography (No. II.), and education (No. III.). The last day for receiving applications for space is fixed at February 25 next. We are given to understand that an English committee is being formed.

The exhibition will be divided into thirteen groups, comprising altogether sixty-three classes. The inclusiveness of the exhibition

will thus be evident from a brief itemised statement of this classification:—

#### GROUP I.—THE HISTORY OF PHOTOGRAPHY.

Class I.—Apparatus and processes. Positive prints and negatives.

#### GROUP II.—APPLICATIONS OF PHOTOGRAPHY TO SCIENCE.

Class II.—Stellar photography.

Class III.—Cinematography.

Class IV.—Geology.

Class V.—Natural history.

Class VI.—Medicine.

Class VII.—Meteorology.

Class VIII.—Photographic surveying (photogrammetry).

Class IX.—Micro-photography.

Class X.—Oceanography.

Class XI.—Chemistry and physics.

Class XII.—Radiography. Apparatus and materials for X-rays. Radiographs.

In this group the exhibition is assured of support from, and co-operation of, a large number of scientific institutions in France and other countries, including the Collège de France, the Museum of Natural History (Paris), the Paris National Observatory, the physiological station of the Parc du Princes, the Marey Institute, the Institute Pasteur, the Faculté de Médecine, the Sorbonne, the School of Pharmacy, the School of Mines, the Smithsonian Institute (Washington), the meteorological observatories of France, the anthropometric service in Paris, Colonel Laussedat and photogrammetric services in France and other countries, the School of Physics and Chemistry, the International Laboratory of Weights and Measures, and zoological institutes in France and other countries. Daily lectures and demonstrations by leading exhibitors are to be a feature of this group. In each class are to be included both instruments and results, and it is anticipated that a complete collection will be of the greatest service to science as well as to photography.

#### GROUP III.—EDUCATIONAL.

Class XIII.—Applications of photography to education and instruction. Apparatus and photographs, including a representation of the work done in France in distributing millions of photographs, and lantern slides for educational purposes, through special postal concessions granted by the Government.

Class XIV.—The teaching of photography. Methods, apparatus, and installations.

#### GROUP IV.—AMATEUR AND PICTORIAL PHOTOGRAPHY.

Class XV.—Pictorial photography by amateurs of the French and other schools, exhibited in sections, each devoted to one school and the work of individual photographers. Examples of apparatus and special processes, negatives, and prints.

Class XVI.—Societies and other bodies of amateur photographers.

Class XVII.—Individual amateurs.

Class XVIII.—Collections of documentary photographs. Photographic record and survey.

#### GROUP V.—PHOTOGRAPHIC PERIODICALS.

Class XIX.—Journals and other publications devoted to photography.

#### GROUP VI.—PROFESSIONAL PHOTOGRAPHY.

Class XX.—Photographic portraiture. Apparatus and photographs.

Class XXI.—Photographic work for amateurs.

Class XXII.—Foreign professional photography.

Class XXIII.—Photo-miniatures.

Class XXIV.—Photographic decorations.

Class XXV.—Photographic enamels.

Class XXVI.—Photography for artists

Class XXVII.—Photo-sculpture.

#### GROUP VII.—PHOTOGRAPHIC PUBLICATIONS.

Class XXVIII.—Photographic reproductions of works of art.

Class XXIX.—Collections of topographical and photographic views.

Class XXX.—Picture postcards.

#### GROUP VIII.—PHOTOGRAPHIC MATERIALS.

Class XXXI.—Plates, films, and papers. Public demonstration of manufacture.

Class XXXII.—Photographic manufactures.

#### GROUP IX.—APPARATUS AND ACCESSORIES.

Class XXXIII.—Cameras and accessories.

Class XXXIV.—Optical instruments.

Class XXXV.—Photographic accessories.

Class XXXVI.—Cinematographs and accessories.

Class XXXVII.—Apparatus and accessories for projection.

Class XXXVIII.—Stereoscopic photography.

Class XXXIX.—Apparatus for washing negatives and prints.

#### GROUP X.—PHOTO-MECHANICAL PROCESSES.

Class XL.—Line photo-etching.

Class XLI.—Half-tone etching.

Class XLII.—Collotype.

Class XLIII.—Photogravure.

Class XLIV.—Three-colour half-tone (printing in three colours).

Class XLV.—Rotary photographic printing.

#### GROUP XI.—INDUSTRIES RELATED TO PHOTOGRAPHY.

Class XLVI.—Chemical substances used in photography.

Class XLVII.—Raw materials for photographic manufacturers.

Class XLVIII.—Mechanical appliances used in photographic manufactures.

Class XLIX.—Leather dressing.

Class L.—Binding, albums, stationery, etc.

Class LI.—Picture framing.

Class LII.—Gilding, silvering, etc.

Class LIII.—Furniture and accessories for photographers.

Class LIV.—Measures, balances, etc.

Class LV.—Artificial light, and apparatus therefor.

Class LVI.—Heating apparatus.

Class LVII.—Motive power.

Class LVIII.—Regulators, chronometers.

Class LIX.—Tourists' requisites.

Class LX.—Means of transport.

#### GROUP XII.—PHOTOGRAPHIC ILLUSTRATIONS.

Class LXI.—Technical works on photography.

Class LXII.—Books and periodicals, illustrated by photography. Photographic illustration in the daily press.

Class LXIII.—Photographic illustrations in catalogues. Photographic posters in monochrome and colours.

#### GROUP XIII.—THE PHOTOGRAPHIC TRADE.

Class LXIV.—Photographic supplies.

Class LXV.—Dealers in photographs and post-cards.

THE Frey photo-litho colour process, which we reviewed on its first demonstration in London almost exactly a year ago, has been recently brought to our notice by a number of specimens produced by it which we should have liked to have exhibited among the examples of colour-photography now on view at these offices, but selected only from photographic, not photo-mechanical, processes. The process, we understand, is a bitumen one, but the beautiful colour effects are due to the firm's skilled practice of photo-lithographic printing. We hear that the process is being taken up by leading photographers desiring large editions of their works, and certainly for such purposes the process has much to recommend it. Inquiries respecting it will be answered by Messrs. W. G. Bruce and Co., 35, Surrey Street, Strand, W.C.

CINEMATOGRAPHY IN COLOURS.—Many rumours having been in circulation in regard to the projection of animated pictures in colours, a good deal of interest may be expected to be taken in a demonstration of cinematography in colours which will be given this, Friday, evening at the Royal Institution, London, before Lord Rayleigh and other scientific men. Captain Lascelles Davidson, who will undertake the demonstration of the method worked out by himself, is one of the exhibitors in the present exhibition of colour photography now open at these offices, where his "snap-shots in colour" have attracted a considerable amount of attention and speculation. The chief merit of his achievement, of the success of which the public will thus have an opportunity of judging, lies, we believe, in the means taken to secure the negative colour-records with the necessary rapidity. The projection methods will be familiar to those who have followed Captain Davidson's patents of recent dates.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."*

The following applications for patents were made between January 8 and 13:—

**X RAYS.**—No. 481. Improvements in devices for the measurement of X rays. W. Ironside Bruce and Edward Sanger Shepherd, 12, Heath Hurst Road, Hampstead, London.

**RELIEF PRINTING.**—No. 996. A method of printing from a surface in-relief. A. G. Bloxam, for the Neue Photographische Gesellschaft, Berlin, Germany.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**WATER-DEVELOPING PLATES.**—No. 26,066, 1904. The invention consists of a photographic plate or film bearing on itself a dry developing mixture compounded with borax, and for development by the application of water only. The following chemical formula, containing borax as a preservative alkali, is the standard, and can be readily made into a paste, which can then be conveniently placed on the plate, film or other vehicle, viz.:—Metol, 2 grains; hydroquinone, 4 grains; potassium metabisulphite (powdered),  $\frac{1}{2}$  to 1 grain; borax, 10 to 20 grains; colloid, q. s.; glycerine, q. s. (optional for assisting solubility). The paste formed of the above ingredients may be manipulated with a paint brush or other device for making a layer or coating the same, on the back of the plate flat or roll films or backing paper, attached to them. When the plate or film requires developing, it is only necessary to place the same in water, when the chemicals will be dissolved and the picture will develop in the usual manner. By this device developer can be readily carried about and plates and films sold with the ordinary chemicals self-contained will be found to be most useful, especially in country places where the chemicals are difficult to obtain, but where water is always accessible. Each plate, or film, or band of the same may contain the necessary quantity of developer for the surface to be developed. The additional thickness formed by the extra coating does not interfere with the "roll" films in any way, as there is ample space therefor, including an additional backing of protective paper or other substance, which may be employed between the chemicals and the usual black paper. William Fraser Claughton Kelly, 22, Winchendon Road, Fulham, S.W., and John Arthur Bentham, 51, Claverton Street, London, S.W.

**A FILM PACKAGE.**—No. 29,631, 1905. A wrapper A for the films B is formed of opaque paper (or other material) by folding or pleating it into a number of folds, into or between which the sensitised films B are placed, each film being protected back and front by the opaque wrapper. The opaque wrapper A is placed in a container or envelope C, from which it can be drawn, leaving the film behind it therein. The container or envelope C is constructed with a partition c dividing it into two compartments, into one of which the wrapper A enfolding the films is placed and a bar or roller D, by which the film is diverted and passed over from one compartment of the envelope to the other, and is provided with a light tight slit e<sup>4</sup> through which the opaque wrapper is withdrawn. One side of the envelope or container is also provided with an exposure aperture e<sup>3</sup> through which the films are successively exposed. It is made from thick cardboard or other light material entirely separate and detached from the camera and entirely closes and seals up the sensitised films therein so that it can be placed in and removed from the camera in daylight without the possibility of any light reaching or damaging the films. The user takes the film pack—as loaded and sealed by the manufacturer—removes the outside sheath and discards it or reverses it, and places the pack in position in the camera, and before exposure pulls the protruding end of the wrapper A a

distance equal to one pleat. This uncovers the exposure aperture of the envelope, which allows the front film to be exposed through the exposure aperture in the fold of the wrapper. After exposure of the film the wrapper is again pulled the distance of one pleat, the exposed film being thereby lifted over the bar or roller D and transferred to the back behind the other films; this operation is repeated until all the films are exposed when the last fold of the pleated wrapper closes the exposure aperture. Instead of or in addition to the folds of the wrapper A the exposure aperture in the envelope may be closed by a cardboard or stiff shutter or by an opaque film or other device. Where the opaque wrapper A is made without exposure apertures in the folds, the first withdrawal of the wrapper for the distance of one pleat uncovers the exposure aperture in the envelope, and at the same time lifts the film carried in that fold in an upward direction, turns it over the deflecting roller or bar D and pushes it down in front of the first or front fold ready for exposure at the aperture. A fresh film is brought from the back of the package and placed in front of the one previously exposed every time the wrapper is pulled. When the last has been exposed the last fold or pleat is drawn over to close the exposure aperture. John Edward Thornton, Rokeby, Altrincham, Cheshire.

**A CHANGING BOX.**—No. 16,390, 1905. The claims for novelty embody a box, one wall of which is movable and connected to the box by flexible material, in which shelves are provided: the

material being held upright and extended. The box can be used as a carrying case for the camera and other apparatus. Arthur Richard Kellaway Jeffery, 2, Cross Street, Lynton, Devon.

The following Complete Specification is open to public inspection before acceptance under the Patents Act, 1901: Copying Prints, No. 25,040, 1905. Method of and machine for copying photographs, pictures, and the like. Clarke.

THE "Photo Era," our contemporary of Boston, U.S.A., has reduced the size of its page with the commencement of its 1906 volume, and shows other signs of keen vitality, not the least of which is a proposition to unite the Photo-Secession and the American Federation of Photographic Clubs. By the latter, we learn, the proposal has been cordially received, but the most that can be said of the attitude of the Photo-Secession is that the overtures have met with "respectful" audience.

An Exhibition of Modern Pictorial Photography is now being held at the Little Galleries of the Photo-Secession, 291, Fifth Avenue, New York. It consists of modern French pictorial photography (gum-prints). Some very interesting pictures are being shown, including several colour experiments, which certain of the French pictorialists have made their hobby, notably M. Puy, who has exhibited specimens of this process at the Photographic Salon in London.

## New Apparatus, &c.

The "Sickle" No. 1 Postcard Printing Apparatus. Sold by O. Sichel and Co., 52, Bunhill Row, London, E.C.

The universal demand for postcards among every class of society has been the means, we are glad to say, of putting money into photographers' pockets, not only through the sale of reproduction rights to publishers, but by the production by the photographer himself of cards which create their own demand locally. Labour

being an important item in the production of the printed cards, those who have embarked, or propose embarking, on this class of business have good reason to make a note of a new piece of apparatus designed

deal rapidly and automatically with the exposure of the sensitive bromide or gaslight cards. The external views of the apparatus, supplemented by a brief description, will suffice to make clear the mode of action of the new machine which has just been placed on the market by Messrs. Sichel. It consists of three portions or chambers,

a magazine or feed reservoir; an exposing chamber; and a collecting box in which the exposed cards accumulate. The feed reservoir, seen as the tower on the right of the figure, holds 500 cards, which are placed in it in a particular cross formation, which is easily understood on referring to the printed directions. The exposing portion is seen in the second figure, where the frame holding the negative is turned back. Negatives up to  $5\frac{1}{2} \times 7\frac{1}{8}$  inches can be accommodated, and by an ingenious provision they can be inserted wet into the carrier and printed in this state, an important advantage when, as is so often the case, the success of a postcard on the market depends upon it being on sale with the utmost promptitude. The negative is simply squeezed upon a clear celluloid carrier. There is also provision for vignettes above the negative, and the insertion of a negative is made in such a way that the charge of unexposed cards in the reservoir is not in any way disturbed. The collecting box takes the form of a drawer on the right of the apparatus, and its construction is such that the very act of withdrawing it from the printer closes it against light. The exposed cards are then carried to the dark room for development.

The method of operating the machine is extremely simple. The magazine being charged and the negative in position, the finger on the scale, on the right of the box, is set to the number of seconds exposure found necessary by a previous trial in a printing frame. This adjustment once made, each card automatically receives the same time, and simultaneously with each exposure a counter records the total number of cards which have been transferred to the "exposed" drawer. The action by which these transferences are made is that of the lever shown, with its handle, in the figures. One stroke from left to right brings the card flatly and firmly against the negative and commences the exposure—which automatically closes. A second (reverse) stroke from right to left removes the card, and the operation is repeated as rapidly as the length of exposure will permit. The illuminant may be daylight or any convenient artificial light, of sufficient power to permit of full exposure of the card within the range of times provided by the apparatus, namely, 2 to 60 seconds. The whole apparatus is strongly made and appears to us to be free from liability to get out of order. Messrs. Sichel inform us that they will be pleased to demonstrate it at their premises at Bunhill Row, and our advice to makers of postcards on anything approaching a large scale is to make themselves acquainted with the machine.

The Universal Palmos Camera: and the Zeiss Pack Slide. Made and sold by Carl Zeiss, Jena and London.

Folding cameras of the hand-stand pattern have been produced by the celebrated Zeiss works during the past year or two, and several have been reviewed in our columns. Now a new instrument has been submitted to us, the feature of which is its wide range of movements. The Universal Palmos, as it is called, is made in one

1112.

size only—namely  $9 \times 12$  centimetres, a standard size on the Continent, coming between our quarter-plate and  $5 \times 4$ . The camera is built throughout of light metal, and can thus be depended on in all trying conditions of climate. Its extension is 14 inches, a length which permits of the use of the single component of a double lens. At the same time a lens of very wide angle can be employed by a device whereby the baseboard of the camera drops out of the way, a short runner adaptor taking its place and providing for the limited range of movement required by a lens of such short focal length. The front of the camera is similarly provided with a great range of movements up and down. Focussing is by scale or by a ground-glass screen, and

the instrument is thus available for the most varied kinds of photography, telephotography, and interior work, as well as out of doors in the hand. In the matter of exposure the camera is made to take dark slides, the Palmos roll-holder, the Palmos film adaptor for the Kodak film pack, or the new Zeiss Pack Slide. All or any of these can be carried, and fit the camera back without alteration in the register. The figures show the camera in three positions, and will give an idea of its movements better than a lengthy description. The lens recommended for it is the Double Protar of 143 mm. focus, and the Protar  $f/18$  for wide-angle work. The whole apparatus, we need

scarcely say, to those who know the quality of the Zeiss manufactures, is beautifully made, substantial though light, and evidencing in its details a thought for the convenience of the user and a skill in obtaining that convenience which few firms can equal. Prices of the equipment and of the lenses are set down in an illustrated circular of the camera, issued by the firm from Margaret Street, London, W.C.

The Zeiss Pack Slide referred to in the above description of the Universal Palmos is a new accessory, emanating from the Zeiss factory, for the exposure of cut films. It is a stout paper envelope which carries one piece of cut film. The envelope is inserted into an adapter

about the size of an ordinary dark slide, the outer shell of the envelope completely withdrawn when the film is left ready for exposure. The shell is then replaced—the operation we find is quite easy—and the film, in its light-tight envelope, is placed with others which have been similarly exposed. The system is extremely simple, as far as we can see, entirely free from liability to break down, and permits of the carriage of an indefinite number of films, while at the same time each exposure can be treated individually. The films listed as supplied in the Zeiss Packing are "Edwards," "Agfa," and "Perotto Green Seal."

## New Materials.

The Page Croft Pigment Paper. Sold by J. Page Croft, 24, Quadrant Chambers, New Street, Birmingham.

With the gum-bichromate process in high favour among pictorial workers there should be a very widespread reception of a paper which offers all the facilities of the home-made gum paper without any of the troubles involved in its preparation. What those facilities are we have never sought to conceal from our readers. We have insisted that the process in which the photographic pigment image can be wiped away by hand to any extent may produce results which are to all intents and purposes non-photographic in character. Perhaps none the worse for that, but not necessarily any the better. In other words we have resisted the view that a gum-print must be something artistically great because it is a gum-print. It may be as good—artistically—as skill can make any print: equally it may be a thing as artistically bad as ignorance and ineptitude can be guilty of. The latitude of the process works for and against it. A Demachy may exalt the process to the zenith, or the dabbler may hold it up to ridicule. At any rate, none may say that the practice of the process involves the difficulties or troubles which are supposed to beset the experimenter in the gum-bichromate process. We cannot profess any but the slightest acquaintance with the practice of gum, but we have nevertheless found the Page Croft paper quite easy in manipulation. The instructions put its speed down at twice that of P.O.P., but our experience certainly makes us think it considerably more rapid than that. On a dull day, when prints on P.O.P. required nearly a couple of hours to print out fully, the pigment print was fully developable after twenty minutes' exposure. The golden rule is avoid over-exposure and to work with the developing water at a low temperature and with the minimum of alkali. In this way prints of the greatest richness are obtained, but with very great over-exposure—so great as to produce a visible image on the paper—the development of the paper can still be forced with hotter water, with added alkali or by mechanical aids. Not that the results are equally good, though we have seen gum-prints of like character lauded as works of genius.

The prints can be developed automatically in water, in which case the results are reasonably uniform; or they can be treated locally with hot water or with a soft brush for the production of any effects procurable by removing the pigment; in other words, affording all the means of control for which your pictorial worker cries.

To sum up, the paper is the essence of simplicity, sensitised in a minute and a half by immersion, dried in half an hour or so in a warm room, exposed rapidly, and developed and ready for drying in less than a quarter of an hour. It can be purchased sensitive or insensitive in the following tints:—Black, cool sepia, warm sepia, and Bartolozzi red. The prices are based on 1s. 3d. for a dozen half-plate pieces.

A NUMBER of new lines in postcards and views specially offered to photographers from their own negatives and photographs have been shown to us by the firm of O. Flammger (Stengel and Co.), of 39, Redcross Street, London, E.C. The firm specialises in the first production of attractive and, we must say, highly saleable cards and views from photographic originals, and we can quite believe their experience that a print for which a very moderate sale can be made in its ordinary state can be converted into a rapid seller when reproduced with embellishments of various kinds. Messrs. Flammger have four chief series, their glazed bromide, and smooth "Platinotone"—apparently a very good colotype—and two series of cards coloured, by hand and machine. Each of these processes proves, in their hands, capable of altogether handsome results, and we cannot do better than draw attention to the firm's offer to send samples on request, as that course will convince our readers more than anything we can say, and will save us the employment of superlatives. One special item we may commend, and that is a series of local views, issued as postcards, and as souvenir cards, 8 x 6 inches, in each case with the arms of the borough introduced in an appropriate manner in one corner. Messrs. Flammger will prepare cards in this style, in sets of not less than 500 each, for any series of photographs.

RECEIVED.—"Silvo" postcards. Sensitised bromide and gaslight

postcards for producing prints on with a silver-like lustre. The emulsion is applied to an aluminium surface. (The Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, E.C.) We shall report on these cards as soon as we have made a few prints on them.

MESSRS. Houghtons, Limited, 88-89, High Holborn, London, W.C., send us a convenient gas-burner for the dark room, consisting of a eye-pass attachment, the watch flame in which is protected from draughts by a circular chamber with mica windows. The accessory is made in brass, and costs, ready for use, only 2s. 6d.

#### CATALOGUES AND TRADE NOTICES.

A HIGHLY decorated diary for 1906 reaches our table from the photographic department of the Actiengesellschaft vorm Gustav Ritzsche, Berlin, makers of Vidil films.

"New Cameras for 1906" is the title of a very lengthy and comprehensive list which Messrs. Houghtons have just issued. It describes and illustrates practically every type and form of hand and camera, including, of course, the celebrated Sanderson series. We note also the description and specification of the new "Houghton" film envelope and adapter, a small accessory no larger than an ordinary dark slide, but providing for the exposure of cut-films ad infinitum.

## News and Notes.

THE Berlin Photographic Company, of 133, New Bond Street, have been appointed Fine Art Publishers to his Majesty the King, by Royal Warrant.

A "ROTARY" TOUR.—We learn that the Rotary Photographic Company, Limited, have just despatched their Mr. C. E. Hodges on an extended tour of the Colonies, including Egypt, India, Australasia and Canada. Besides carrying "Rotary" papers, postcards, films, etc., Mr. Hodges is also representing the pictorial postcard department, with the well-known series of "Rotary Picture Postcards."

PHOTOGRAPHIC reproductions of the works of Frank Brangwyn are being published by Alvin Langdon Coburn (from 89, Guildford Street, W.C.) whose one-man show at the Royal Photographic Society will be opened at Russell Square on February 6. At present two portfolios have been completed, each including five reproductions. The price of each portfolio is five guineas.

THE third annual exhibition of the Dover Institute is announced for February 14 and 15. There are four open classes. The Rev. C. Lambert, M.A., is the judge; the secretary, Mr. J. W. Jewells, 6, Gladstone Terrace, Dover.

PHOTOGRAPHIC Society of Ireland.—The annual exhibition will be held in the Leinster Hall, Molesworth Street, Dublin, from April 2 to 7, when exhibits in ten classes will be judged by Mr. Arnold Baker. The last day for receiving entries is March 24. The secretary of the exhibition, Mr. W. F. Cooper, 194, Clonliffe Road, Muncondra, Dublin, will send the entry-form and prospectus to any applicant.

THE exhibition in Paris, under the patronage of the Photo-Club, for portraiture and other photography done with anachromatic lenses is to be opened at 44, Rue des Mathurins on March 1. It will be remembered that we published several articles on these lenses, of which M. Puyo and other leading pictorialists in France have spoken very high praise for their particular purposes, and the exhibition will be of more than ordinary interest to the professional photographer looking for certain qualities of breadth in his portraiture.

FROM Editor, Thomas Harrison Cummings, of the "Photo Era," Boston, we have received a reprint of the address delivered by him to the Convention of the Photographers' Association of America "Photography: Its Recognition as a Fine Art and a Means of Individual Expression."

NEW work on copyright is announced by Stevens and Haynes, of 4, Yard, Temple Bar, namely, "International Copyright," by Wilfrid Briggs. If the author is able to clear up some of the intricacies of foreign and colonial copyright, his work will be worth all the price

of it (16s.). We see that he does treat of artistic copyright in relation to photographs, but we doubt whether there is anything fresh to be said which will illuminate the dark places of this branch of the subject.

AN Argument for Stereoscopic Photography.—The "Dioptric Review" reports two interesting cases from New York where a complete cure of squint has been obtained by the prolonged use of glasses and stereoscopic exercises. In the first case it was after two and a half years of use of the stereoscope and correcting glasses that the intermittent strabismus ceased. The second patient was cured by the wearing of glasses and exercises which involved exclusion of the sound eye at intervals and the use of the stereoscope.

THE Secretaries' Postal Photographic Society.—Mr. B. J. Mitchell, having resigned his position as secretary, Mr. S. G. Kimber, Oakdene, Highfield, Southampton, now occupies the position, and will be pleased to give particulars to any hon. sec. wishing to join.

THE Cripple Gate Photographic Society's seventh annual exhibition will be held in the spacious hall at Cripple Gate Institute, Golden Lane, E.C., on March 12 to 15, 1906. Entry forms are now ready. Full particulars and entry forms may be obtained from the Hon. Sec., John B. Parnham, 5, Reighton Road, Upper Clapton, N.E.

A GERMAN edition of one of Mr. Kearton's nature books has been issued by the well-known firm of W. Knapp, under the title "Tierleben in freier Natur," and at a price of 10s.

A NOVELTY in the way of supplements in magazines is to be provided by the "Camera" (Philadelphia) in its February issue. It will be a Velox print coloured by the Japanese Water-Colour Co.

## Photo-Mechanical Notes.

### The Penrose Pocket Book and Diary, 1906.

The second issue of this convenient little diary reaches us from Messrs. A. W. Penrose and Co., 109, Farringdon Road, London, E.C., with a repetition of the arrangement of formulae and tables drawn up by Mr. William Gamble. These include a number of optical and chemical data in addition to the working directions for the half-tone, line, and three-colour processes. We know that the volume has been a constant source of reference to the photo-engraver, and doubtless many readers of these notes will be glad to know that Messrs. Penrose will send a copy to any bona-fide process applicant.

### Main Pipes for Photo-Engravers' Sinks.

The advice of a plumber to readers of the "Meard Printer," who had experienced trouble in the action of waste acid and alkaline solutions on drain mains, may be noted by others who find themselves in similar difficulties. "Properly glazed earthenware sewer pipe is the best for waste water containing acids or strong alkalis. The trouble with the ordinary glazed sewer pipe is that the clay of which it is made contains iron; this is attacked by the acids through the glaze and the whole pipe soon absorbs water and becomes useless. Proper sewer pipe for this purpose is made of 'magnetized clay,' that is, clay that has been poured in a fine stream before a powerful magnet that attracts all the particles of iron from it. The glaze must be acid proof and the pipes should be molded in lengths of at least four feet to reduce the number of joints required. The joints should be first calked with asbestos packing and finished with retort cement. The best material for sinks is undoubtedly soapstone, put together with hydraulic cement. All serviceable plumbing must be so supported that its weight or vibration does not injure the joints."

### PHOTO-MECHANICAL PATENTS.

The following patent is open to public inspection before acceptance under the Patents Act, 1901: No. 26,965. Photo-Mechanical Printing. Ippers.

The following application for patent was made last week: No. 644. Apparatus for photo-mechanical printing. Benjamin James Hall, 41, Castelnau, Barnes.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 16. Rev. F. C. Lambert, M.A., in the chair. Mr. S. G. Kimber read a paper, with lantern illustrations, on "Winchester Cathedral," the interest of which was chiefly architectural and archaeological, and was created in large measure by the excellent lantern slides from the lecturer's negatives which accompanied it. Mr. Kimber reminded his audience that Winchester was the *pièce de résistance* in the programme of the Photographic Convention at its meeting at Southampton in July next, and probably the members of the audience with a penchant for architectural photography could have no stronger incentive offered to them to attend the forthcoming meeting than the lecturer's demonstration of the subjects which awaited them at Winchester.

Meeting held January 23, Mr. S. H. Fry in the chair. A demonstration of portraiture with the "Ideal" flash-lamp was given by Messrs. Houghton. Mr. Chas. E. Houghton explained the con-

struction of the lamp. It consisted of a framework, which he might call the "cabin," covered with fireproof fabric within which the magnesium flash was produced, being ignited by means of a percussion cap of the "central fire" type. The magnesium smoke was entirely retained within the lamp, and the latter was removed from its stand and emptied of its contents through a window or by any convenient means. A demonstration followed, in the course of which a number of portraits were taken instantaneously and developed on the spot. It was stated that the weight of powder consumed for each exposure for a head and shoulders was 15 grains, that the cost was 3d., and the time of exposure as short as one-eightieth of a second. In reply to a number of questions, the demonstrator said that the two parts of the powder should be mixed at the time of use, but that he had found the mixture to keep for some time. A member of the audience who worked the lamp with great satisfaction in his business stated that he had found the mixture to work well six months after mixing. He also used two lamps in one "cabin" for two exposures in quick succession. It was pointed out that the fabric of the "cabin" could not catch fire. On one occasion on which the lamp had been charged with a heavy dose of powder, for photographing 150 people, the only effect had been to make a charred hole in the material of the illuminating chamber. Mr. Frank Turner asked how it was possible for a photographer to judge of the effect he was getting with the lamp when photographing subjects in which there was a good deal of light drapery. It was recommended to use an ordinary gas or lamp light when viewing the sitter on the screen, but Mr. Turner did not think that the same effect would then be observed.

A demonstration of the Boardman arc lamps was then given by the Boardman Electrical Patents Co., Limited, assisted by Mr. Kaye. Mr. Boardman explained that the lamps provided for the visible adjustment of the lighting on the sitter in any desired way, and it was shown how the use of a reflector produced soft effects without loss of roundness and relief; also that the interposition of a semi-transparent screen between the lamp and the sitter gave a range of contrasts from strength (almost hardness) to softness which was really flatness, according as the filter was close to or removed from the light. This effect of the filter was very clearly shown by the operator. As regarded the choice of a lamp, it was stated that one taking three pairs of carbons would enable the photographer to work on voltages from 100 to 240 volts, and with direct or alternating current.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

#### MEETING OF THE COMMITTEE.

A MEETING of the general committee was held at 51, Baker Street, W., on Monday, 19th inst. Present: Messrs. F. A. Bridge, Alfred Ellis, S. H. Fry, Wm. Grove, A. Mackie, H. S. Mendelssohn, D. Prodder, E. Scamell, Lang Sims, and R. Fellows Willson. Mr. Alfred Ellis, Past-President, in the Chair.

The Assistant-Secretary reported that the sub-committee appointed in connection with the Assistants Certificate Scheme, had carefully considered all the letters they had received from assistants criticising the present regulations and conditions. The principal objections raised were in respect to the fees chargeable and to the existing classification. Several very sensible letters had been received, and the sub-committee were glad to acknowledge the value of many of the suggestions that had been made. It was noticeable that in several cases the writers of letters made complaints for which there was no ground, and which were based upon erroneous interpretation of the conditions of the prospectus. The report of the sub-committee was as follows:—The sub-committee recommend that the association should be prepared to grant certificates to general assistants based upon their own statement of their qualification, confirmed by present and previous employers, to be known as the General Assistants' Certificate. That a registration fee of 2s. 6d. be charged for a certificate of this description. That at present no other alteration be made in the conditions already published.

After discussion the report was adopted, and the sub-committee were composed to make the necessary arrangements for carrying out the recommendation into effect.

The meeting then became special for the purpose of nominating

President and twenty-four members of committee as the committee's nomination for the new committee.

After the close of the formal business, the Chairman alluded to the very pleasant gathering the committee and friends had the early part of last year at the Villa Villa Restaurant, and suggested a similar festivity should take place this year. The suggestion was unanimously adopted.

**MEETING OF THE HULL BRANCH.**—A meeting was held January 10 at Regent House, Messrs. E. Cooper, C. Delf, W. Duncan, W. Fussey, R. Garside, P. Lyne, T. C. Turner and A. Wellsted attending. Letters expressing regret for absence were read from Messrs Barry and Parkyn. The Chairman (Mr. A. Wellsted) said he was glad to meet the members again, and regretted that the interval had been so long. Various causes contributed to render the activity of the branch subject to fluctuation, but he was quite sure that every one present continued to regard the Association's work with interest and sympathy. He wished the members every good fortune during the year. The Hon. Secretary drew attention to the reports of a considerable increase in the system of invitation sittings among professionals in Hull, and thought that nothing but mutual consideration would be effective in limiting this acknowledged evil. Prospective sitters came to the studio armed with an invitation from another man and endeavoured to cut down terms. Ladies, who received these baits, also seemed anxious to acquaint their friends in the city of the fact, and it led to mischievous retaliation or general loss among photographers. The chief discussion of the evening related to the practice of several outside enlargement firms who were operating in the city on an unusually aggressive scale and with much artfulness. Mr. Garside mentioned the names of several people who had asked his advice as to means of proceeding for the recovery of valued originals, and he wished to know if the committee in London were prepared to take up any test case with a view to giving publicity to the business. If not, he could find people who considered themselves very badly used. Mr. Fussey said the city was overrun by canvassers (chiefly women), the firm employing thirty-eight people. The procedure was to make large and faint bromide print, and to suggest that this was merely the "sketch" of a fine and important work which could be obtained for small weekly payments. After a few weeks of these payments the old frame trick was sprung upon the dupe, and in the end sums varying from 15s. 6d. to 50s. were obtained for the greatest rubbish imaginable. When the people objected they had to face the loss of the payments already made and the retention of the original photograph, and rows were constant incidents of these schemes. The harm done to professionals was of a two-fold character. Firstly, the direct loss of orders, which would otherwise be executed of fair value, and, secondly, because when the scheme had been worked out a great prejudice would remain against photographic enlargements through the fear of being done again. Mr. Cooper said the railway company delivered frames by the trolley load, and there was no time to lose. Mr. Delf suggested that every photographer should display a notice in this window dealing with the matter, as it was a cheap and effective means of reaching the notice of the public. Messrs. Fussey and Duncan thought a handbill circulation should be used as a countermove. The Hon. Secretary drew attention to the valuable assistance received from the Press, and it was agreed that the following extract from the "Hull Daily News" should be printed and distributed among all photographers for window exhibition:—

#### CAUTION.

I hope this note may catch the eye of Major Malcolm, Chief Constable of Hull, and his detective department. At the present time the city is swarming with a set of individuals who are practising in suburban streets a piece of smart American trading. They call on houses, and offer to enlarge portraits and finish and frame them for a fixed sum. After taking a deposit they return in a few days to say that the style of frame ordered is already sold out, and they therefore, only supply immediately one of a higher price. Most of their clients protest, and then they either have to lose their deposit and look pleasant. The visitors usually come when the husband is at work, and are not unequal to getting to the windward of a fair sex as have no business knowledge. It may possibly be the province of the Chief Constable to issue a warning against these folk, who sail, I think, sufficiently close to the wind to need

stopping. The moral is easily learned when there are so many old-established respectable photographers in the city. Entrust your work only to them.

**SUTTON PHOTOGRAPHIC CLUB.**—On January 19, Mr. C. Thwaites, M.I.C.E., gave a lecture on "Eclipse Photography." Mr. Thwaites' lantern slides of the sun, moon, nebulae, stellar bodies, and of the places and people connected with various expeditions he had taken part in, proved to be most interesting, as were also his reminiscences.

**BRADFORD PHOTOGRAPHIC SOCIETY.**—The annual meeting was held at the Grammar School on January 15, when Mr. G. A. Bever was re-elected President for a second year. The new secretary is Mr. W. H. Womersley, Spring Hurst Road, Shipley, and other officers, are as follows:—Vice-Presidents, Alex. Keighley, F.R.P.S., E. Clough, A. Bracewell, W. C. Ramshaw, G. Thistlethwaite, and Percy Lund. Committee: Messrs. H. A. Ram, J. Dawson, A. Denbigh, W. E. Fearnley, F. W. Linck, F. Nicholson, J. F. Seaman, A. R. Sharpe, J. Smith, G. Wood. Lanternists: Messrs. W. J. Forrest and T. Steele. Librarian: C. P. Tatham. Secretary of Portfolios: J. H. Liebreich. Treasurer: E. Hill. Assistant Treasurer: S. Hampshire. Recording Secretary: H. W. Longbottom. Secretary: W. H. Womersley, Spring Hurst Road, Shipley. Assistant Secretary: W. E. Townsend.

At the Chelsea Society on January 18 a lecture on "Holidays in Ireland" was given by Messrs. Brown and Hurdman.

**BROMLEY CAMERA CLUB.**—On Wednesday in last week Miss Gertrude Bacon, daughter of the Rev. J. M. Bacon, delivered a lecture on her visit to India with the eclipse party. Soon after the eclipse commenced they began to experience the strange weird feeling of which they were conscious only at the time of a total eclipse, though it might be likened to the sensation produced by a coming thunderstorm. The marvellous hues they had observed in Lapland were noticeable. Darkness stole gradually over the landscape, and before very long the birds seemed to understand that something unusual was taking place. They began to retire to roost, and the night-flying birds and insects began to make their appearance. The air began to get cold, and things began to assume a yellowish shade. As they took their places at their instruments for the purpose of making observations and taking photographs, their hands trembled and their hearts beat with excitement. Gradually the darkness deepened. It felt like a pall, and then a glorious object, the corona, appeared, an object indeed of indescribable beauty, of which no drawing or description would give them an adequate conception. The stars appeared twinkling close up to the sun, and totality commenced. The photograph of the scene thrown on the screen would give them an idea of the great black ball, representing a dead world, a ghastly corpse. But around it could be seen the great heavenly glory, a lambent, rushing flame, the corona, whilst outside this inner corona there appeared sharply defined streamers, glowing and bright. They were of the utmost brightness and brilliance, with something ethereal in their heavenly loveliness. It seemed as if for a fleeting second the golden gates had swung ajar, and given them a brief glance of the land which lay beyond the veil. There seemed no time for anything. The seconds were flying. The long streamers first disappeared; then the inner corona, though not for ten or fifteen seconds after totality. Venus and Mercury and the stars and the great shadows vanished, and the light came flashing back over the landscape. It was a matchless sight. The photograph thrown on the screen at this time was described as one of the finest ever secured of the corona.

**CROYDON CAMERA CLUB.**—Mr. Jackson gave a practical demonstration of the products of the Rotary Photographic Company on the 17th inst., and an interesting evening was spent. The various brands of bromide papers, including the latest, consisting of an emulsion on a silver-coated support, were described, and it was mentioned that although large differences as to weight, surface and tint existed, the speed of all was the same. The Rotary stripping films for three-colour and monochrome printing, the ordinary carbon tissue and negative paper, were each in turn brought forward, and the method of working them clearly indicated. Mr. Jackson then handed round some excellent examples of three-colour work on paper, also carbon prints and transparencies, and paper negatives. The last-named appeared rather hopeless viewed by reflected light, the images being

veiled and sunk in; by transmitted light they were, however, seen to be capital negatives, and considering the nature of the support remarkably free from grain.

**BURTON-ON-TRENT NATURAL HISTORY AND ARCHÆOLOGICAL SOCIETY** (Photographic Section).—At a meeting, held on January 16, a members' competition in architectural subjects was held. A number of excellent prints were shown, Mr. J. W. Woodhead taking the award with one of the doorways of Lichfield Cathedral. This was taken with an R.R. lens, well stopped down, and time exposure, and was printed on Leto gaslight paper.

**ST. HELENS CAMERA CLUB.**—At a meeting on January 17, Mr. S. A. Buckley gave a lecture on "Commercial Photography." By "commercial photography" he meant something beyond the taking of photographs as a hobby. For business purposes it is often of the utmost importance to be able to take a photograph of something and produce a presentable print in a minimum of time. One simple way of saving time was mentioned. After fixing and rinsing a plate, put a piece of thin celluloid in contact with the film, and squeegee the water out. By this means a print can be taken just as if the plate had been dried. This dodge, in conjunction with bromide paper that will stand heating to dry it, enables one to produce a print very quickly indeed. In reference to the reproduction of photographs in the Press, he mentioned that Gee and Watson's, the London Studio, 20, St. Bride Street, E.C., were agents for all the important papers and bought copyrights for themselves. The lecturer, however, wished to refer to those cases where fairly large numbers of copies were required to illustrate or advertise something in business, or when, as in the case of book illustrations and picture postcards, large numbers were required for sale. Photographic prints on bromide paper can be produced in large numbers by the aid of machinery, but the cost of these photographs, compared with that of prints made by means of printer's ink in a printing press, is very high, and therefore these latter processes are chiefly of interest in commercial photography. What is called the half-tone process is now very largely employed. The print is made up of fine dots of varying size (equal density), formed by means of a network of lines ruled on glass and placed in front of the sensitive plate when making the photographic negative from which the half-tone process block is printed. It may seem that the effect of the network of lines in front of the plate would be to cut the image into tiny squares which would be all the same size, only varying in density according to whether the square happened to be in a light or a shadow, so that when the negative was printed the result would be simply covered with black lines and the picture only imperfectly seen through them. Yet by suitable manipulation the image is broken up into dots, which are of varying size, but of equal density. One way of accounting for the fact that these dots are produced is to suppose that each little aperture in the network of the ruled screen acts like a pinhole; the spot of light formed by the opening in the diaphragm of the lens is an object external to this pinhole, so that the diaphragm is focussed by the pinhole on the plate and produces a black dot. That something of this kind actually does occur is proved by the fact that if the diaphragm opening is made square, the dot is rendered approximately square, the same applying to any other shape of diaphragm opening. The dots vary in size in proportion to the light; where there is most light the dots are largest. Each dot may be considered to start with a nucleus, which grows with greater and greater intensity of light or longer exposure. The screen will be, say, 1-10th inch from the plate. Various shapes of diaphragm are used, but generally the square, or square with extended corners, the object being to produce a dot which tends to spread at the corners, and will thus restore the parts which the screen has cut off. Half-tone blocks are made from negatives produced through screens ranging from, say, 30 to 400 dots per inch. When speaking of screens the number of dots is expressed per inch run, not per square inch. From the negative thus produced is made the half-tone block. A sheet of copper or zinc is coated with fish glue in combination with a bichromate salt, dried, exposed under the negative for about twice as long as for an albumen print. It is removed from the printing frame, immersed in a dye for a minute, so that the development can be watched, put into a dish, and water allowed to run over it until the bare metal is visible between the dots. It is then drained and dried in methylated spirits, heated over a gas stove, and then etched in an acid or iron perchloride bath,

which attacks and dissolves away the metal where it is not protected by the dots formed of insoluble glue. This etching may take from 5 to 15 minutes. The metal plate, when finally mounted on wood, is ready for the printers. The negative must be reversed by means of a process mirror or prism, placed before the lens, or the film must be transposed. Referring to the collotype process, the lecturer said the word "collotype" designated the process of producing a print in greasy ink from a gelatine surface. A glass or metal plate coated with gelatine, in combination with bichromate salts, is exposed under a negative, then washed in cold water for a considerable time to remove the bichromate. The plate is then allowed to dry after which it is placed on a level table and covered with what is known as the etch, the object of which is to damp the plate thoroughly and at the same time to keep it damp as long as possible. This is accomplished by the presence of some deliquescent substance. The plate now has the property of taking up the greasy ink in proportion as it has been acted upon by the light. The parts that have absorbed much water will take little ink, and on this principle every possible gradation is reproduced, according to the amount of action the light has had on the film. A reversed negative must be obtained either by stripping the film or with a mirror or prism. The process requires suitable negatives, extremely soft but full of gradation and detail, which, with transmitted light, have a greyish rather than a black look. By means of a microscope the lecturer showed the difference between various half-tone blocks, screens, and prints.

**HACKNEY PHOTOGRAPHIC SOCIETY.**—A smoking concert was held in connection with the Hackney Society at the Pembury Hotel on Tuesday in last week, Jan. 16, at which, under the chairmanship of Mr. F. W. Gosling, a long and entertaining programme was provided entirely by members. The president, Mr. Harold W. Lane, provided the "star turn" of the evening, in the shape of what was described on the programme as "a development in one act," entitled "The Peer, the Pressman, and the Photographer," the dramatis personæ in which were represented by Mr. Walter Selfe, Mr. J. J. Westcott, and the presidential author. Mr. Lane, as a playwright, is evidently of the modern school, which is prepared to sacrifice conventions, and even continuity of plot, to provide an amusing entertainment, and the reception of the performance was a proof that Hackney entirely approves of irresponsible fun, which is frequently photographic and personal in a good-humoured way. The many other items on the programme were also contributory to the evening's pleasure, and all concerned may be congratulated on a most enjoyable function, to the gaiety of which at the close the chairman, unexhausted by his active conduct of the meeting, added with a "French" song.

**LEEDS PHOTOGRAPHIC SOCIETY.**—The annual general meeting took place on January 16, when the officers for 1906 were elected. T. W. Thornton again holds the office of president, supported by Messrs. Godfrey Bingley and Robert Mackay as vice-presidents. G. H. Rodwell fills the treasurer's position, vacated by Mr. Thos. Carter, while A. Edwards continues the secretarial work. After the conclusion of the business Mr. Godfrey Bingley exhibited selections from a year's lantern slide work, comprising most varied and interesting subjects in Yorkshire, Lincolnshire, and Norway. Mr. Bingley apologized for the slight marking appearing in several of the subjects. He had used roll films, developing some in the Kodak machine with their adjusted pyro-soda developer, while the rest were developed by the ordinary method with his usual mixture of hydroquinone and eikonogen with caustic potash as the alkali. In most cases the negatives by the latter method were marked, while those developed by the machine were free from this defect. In conversation with a Kodak representative, Mr. Bingley mentioned this puzzling experience, and was informed that the Kodak Company did not recommend eikonogen, as they had found it prone to cause markings, the developed result of a slight reducing action exerted by the black paper backing on the emulsion, which did not appear when a developer of a less searching character was used.

**HANDSWORTH PHOTOGRAPHIC SOCIETY.**—At a meeting on Thursday January 18, the president (Mr. P. Whitehouse) gave a demonstration of the Watkins "time" system of plate development. He prefaced his demonstration with a short description of the theory of the process. He explained that it consisted in noticing the time which elapses to produce the first appearance of the image, counting from the time of flooding the plate with developer. As the time taken for complete

and accurate development is always a multiple of the time taken for the first appearance, all one has to know is the number or "factor," for the developer used. The demonstrator explained how and why different developers had different factors, also how one can determine the factor for any developer at the expenditure of two or three quarter-plates. Expose three plates on a normal subject, giving all three exactly the same exposure, which must be as near the correct as possible, using an exposure meter. Then develop one of the plates, noticing both the time taken for first appearance and also time taken for complete development, which, if divided by the time of first appearance, gives the factor for that particular developer. Develop the second plate and use that factor if a perfectly developed negative is obtained. The third plate is not wanted, but if the plate turns out to be either under or over-developed, then develop the third plate, altering the factor to suit the requirement. At the expense of two or three plates the developer is once and for all determined. The demonstrator impressed upon his audience the necessity of always making up the developer of exactly the same composition and always developing at the same temperature. He then proceeded to develop two or three plates with a pyro-soda developer, having a factor 4½. The first plate was normally exposed, and the image made its first appearance in one minute and a half, and was complete in just under seven minutes. The second plate, which was over-exposed, showed a first appearance in 1 min. 13 sec., and was therefore finished in five minutes and a half. Both plates came out very well, very little difference being noticeable. A short discussion followed, which brought forth the merits and demerits of the process. Mr. Proctor, in proposing a vote of thanks to the demonstrator, stated that he was not converted to the system, although he could see that no doubt it was founded on a sound scientific basis; yet the "personal factor" could not be disregarded, the fact that one has to use a certain amount of judgment in noting the first appearance is a big loophole for error, especially when multiplied by a large factor. Dr. W. J. Foster seconded the proposition, which was unanimously passed.

## Commercial & Legal Intelligence.

**A CASE of Likeness.**—In a case at the Westminster County Court, last week, where the price of a hand-painted miniature was claimed, Judge Woodfall, after studiously examining the photograph and miniature by the aid of a large magnifying glass, said that the miniature was not like the defendant; but, on the other hand, neither was the photograph. He also said the artist had painted the eyes blue, but the artist said they were grey.—The plaintiffs were told to alter the painting.

**THEFTS of Photographic Apparatus.**—At Bow Street, last week, John Appleby, aged 30, described as a photographic dealer, having no fixed address, appeared on remand charged with several cases of larceny and receiving stolen property. Mr. Bohn defended. The prisoner was charged with stealing a camera, value £12 12s., from the shop of Messrs. Houghton, photographic dealers, of High Holborn, on November 15 last. On that day the prisoner, it was alleged, called at Messrs. Houghton's shop and asked to see some cameras. Several were shown to him, and he went away without having made any purchase. Shortly after he had left a hand-camera was missed. In support of another charge it was stated that on November 10, 1904, Messrs. Watson and Sons, photographic dealers, received a telephonic message purporting to come from a firm in Cockspur Street, asking them to send some cameras on approval. A boy was sent with two cameras, and on the way he was met by a man who told him he had come from the firm to whom they were consigned, and at his request the boy handed over the parcel to him. One of the cameras, value £8, was subsequently found in the prisoner's possession. The other one had not been recovered. The evidence in the last case was somewhat similar. On October 2 last, in consequence of a telephonic message, the London Stereoscopic Company, Cheapside, handed their errand boy a camera, value £15 15s., to take to a firm in New Broad Street. On the way he was stopped by a man, whom he recognised as the prisoner, and at his request he handed the camera over to him. Detective-Inspector Crouch, of the City Police, deposed to finding the

camera, together with six others, on October 7 last at an address in London Fields, where the prisoner was then living. Detective-Sergeant Hayman said he arrested the prisoner on his release from the Old Bailey last week, where he had been acquitted on similar charges to those now preferred against him. The prisoner, who pleaded not guilty and reserved his defence, was committed for trial.

**MACLAURIN and Co., LTD.** (Photographic Apparatus Manufacturers, London).—Issue on January 1 of £400 4½ per cent. debentures, part of a series created same date, to secure £2,000, charged on the company's undertaking and property, present and future. No trustees.

### COMPANIES REGISTERED.

**STANDARD COMPANY, LIMITED.**—Registered January 12, by P. Ashcroft, Moorgate Station Chambers, E.C. Capital, £1,150, in 1,000 Preference and 150 Ordinary shares of £1 each. Objects: To acquire, work, develop and turn to account the sole rights in a certain secret process connected with the manufacture of photographic paper. No initial public issue. The signatories are to appoint the first directors. Qualification, £5 Ordinary shares.

**BROMAR, LTD.**—Registered January 12. Capital £20,000 in £1 shares (10,000 preference). Object, to adopt an agreement with J. Findlay and F. E. Freeth, and to carry on the business of manufacturers of photographic papers, dry plates, films, cameras, and photographic apparatus, accessories, and chemicals, photographers, lithographers, publishers, chemists, etc. Minimum cash subscription, 3,000 shares. The first directors (to number not less than three nor more than seven) are J. Findlay, F. E. Freeth, R. H. Gillespie, C. D. Gaskell, G. a'Beckett Terrell, E. C. Willis, and Mrs. F. E. Terrell. Qualification, £500. Remuneration (except managing director), £100 each per annum, with £50 extra for the chairman, and £100 each extra in any year when 10 per cent. dividend is paid.

**ART in Picture Frames.**—As with some books the best part is in the cover, so with some pictures the best is in the frame. For centuries, writes the Paris correspondent of the "Standard," it was the custom to border every picture with a wooden frame, bevelled, beaded, carved, or moulded, according to a joiner's taste, and gilded in a style worthy of an advertisement for gold paint. It was, however, photography that taught us that a frame has no special virtue in being gilded. The belief that dark frames were only suitable for colourless pictures is also destroyed, and yet some bold spirits are even now leading us back to primitive truth. One of the few women who have works hung at the Luxembourg is famous as much for her frames as for her style, and now the Countess of Bearn has just given a new frame for the most celebrated picture in the Louvre, Da Vinci's "La Joconde." The frame, like the picture, is old, and is of Italian workmanship. It is carved in a simple but very finished design, and the gilding is like that on no other frame in the Louvre, being quiet but not shabby. The Countess of Bearn has thus drawn attention to the ugly and unsightly frames of which there are so many in the Louvre. Appeals are made for further gifts. So far, there is no response, but the first caused much talk, and since the new frame was put on "La Joconde" attracts its thousands.

**PHOTOGRAPHY in Advertising.**—A new enterprise has been undertaken by Messrs. Elliott and Fry, the well-known West-End photographers, viz., in the domain of fashion illustration. They have issued a costume catalogue, entitled "Photo Fashion Studies," which in itself is a work of art. Living models are employed to aid the presentation of the costumes in wear, with the result that the artificiality which necessarily attaches to the work of even the best of drawings is replaced by a pleasant naturalness. The booklet will advocate more eloquently than any amount of written words the advantages of photographic work in high-class advertising literature, and, incidentally, serve to convince the interested reader that Messrs. Elliott and Fry have realised the necessity of giving of their best in the new branch in which they have embarked. In pose, in detail, and in artistic suggestion the specimens contained are excellent. We quote the above from a review in the "Draper's Record," in order to point out the new and profitable directions in which photography is being applied by those alive to its possibilities.

## Correspondence.

### PLATES OR FILMS.

To the Editors.

Gentlemen,—I am about to carry out an idea, which would require convenient portable apparatus to make at least forty  $\frac{1}{2}$ -plate exposures per day, chiefly buildings; instantaneous apparatus not required. I have had a life-long experience of the ordinary field camera and tripod work, and know that, generally speaking, work done with it is vastly superior to hand camera work, but as the making of at least forty exposures per day is essential to my plan, I am faced by the difficulty of portability. I have had no experience of hand, but if I can hear from experienced men that with care work with hand cameras and films can be done equal to glass plate and ordinary field camera, I shall purchase one, and thus reduce the labour in my plan very greatly. But the quality of result must stand first. After close examination of a great number of films I have come to the conclusion that the material of which the film is made for a basis for the emulsion cannot be made so transparent as the best glass, therefore it is impossible for the result to be so crisp as those on glass, but as I have not worked films I am open to conviction. I should judge the different methods by (firstly) quality of results, (secondly) portability, (thirdly) cost. Your opinion would be greatly valued by

WET PLATE.

[There is no doubt in our judgment, and we believe our experience is that of many of our readers, that negatives, in every respect the equal of those on glass, may be obtained, and are being obtained in thousands, on flexible film. The only consideration which our correspondent need weigh with care is the holding of his half-plate film perfectly flat in the focal plane of the lens. Only in this respect is he likely to experience any disability of films in comparison with glass; but with a well-made roll-holder he ought not to detect any want of definition in his negatives on this account. We shall be glad to have the views of other readers.—Eds. B.J.P.]

### THE "SINOP" PROCESS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have been to-day to see your exhibition of colour photography, and feel grateful to you for the care you have taken to bring so instructive a collection together. The leading feature your visitors will notice, I think, is the curious inequality of the exhibits; some are so very good, and some—otherwise. The gelatinous or "blobby" appearance of most of the prints seems to be the main fault. To remedy this why not use the "Sinop" simplified collotype plates? On the three-colour bed-plate correct registration is easy, especially if a few prints from the yellow plate are printed in black, to register the red plate with. The simplification is so great that a very slight acquaintance with ordinary collotype methods is necessary, while the prints have a crisp, dry, matt appearance, which I think is a great improvement. Although the process involves printing in ink, it can hardly be called mechanical any more than other processes which entail dyes and stains. I enclose a print to show what I mean.—Yours truly,

S. G. YERBURY.

25, Milton Road, Acton, W.  
January 22, 1906.

[The specimen of three-colour "Sinop" is the same subject as No. 6 in the exhibition, and we have therefore placed it on the walls for comparison with the result obtained on "Rotary" stripping pigment films.—Eds. B.J.P.]

### FREE SITTINGS.

To the Editors.

Gentlemen,—I for one am glad to see that one of your readers has spoken out on this iniquitous system.

I have lately joined a large society (not photographers) in London, and the day after my name appeared in its journal as having been elected, I received an invitation from a well-known firm, informing me that they were making a collection of the portraits of well-known men, etc., and inviting me to go and sit free. Now, I do not happen to be a well-known man, not even to the police, and I hope I never shall be, and being a professional photographer, I can obviously obtain as many free sittings as I want.

Personally, I think this class of business is extremely objectionable and likely to ruin any business in the long run, and as you aptly point out, it is a system which is bound to act prejudicially on photography generally.

The cheapening of photography, and the multitude of cheap hand-cameras in the hands of those who are willing to give their friends what they call "likenesses" for the mere cost of materials is bad enough. But I am not afraid of such things, because I know I can turn out far better work, and I see that I get my price for it. In fact, I believe that the very universality of the amateur photographer is an indirect advertisement for the man who turns out first-class work.

It is quite another thing, however, with "free sittings." I have met with cases in which I can trace direct damage to this objectionable custom. I have not yet offered a complimentary sitting to anyone. But I have frequently, when a prominent local person has come to be photographed, asked them to sit for me, and explained what I have wanted the negative for. In most cases I have met with a courteous assent. Some of the people seem sort of tickled at the idea that I think it worth while to take them.

One of my neighbours makes a great feature of this class of business, and I am frequently told of it by my customers. Still, in the face thereof, I hold my own, at least judging from external appearances, and my banking account confirms me in this comforting assumption.

I cordially agree with the concluding paragraph of Mr. Wyrall's letter in your last issue, and though I am occasionally told that Mr. So-and-So down the street will take a sitter for nothing, I courteously refuse, and shall continue to do so.

This is, I think, a matter which the P.P.A. might well take up, and induce their members to agree upon.—Yours faithfully,

A COUNTRY PROFESSIONAL.

[We are glad to find that others share our view of the disastrous effects of the "free sitting" system. The latest variant of it which comes to our knowledge is the case of a firm of photographers offering to take free portraits of people in their motor-cars on the prospect of reproduction fees from the photographs.—Eds. B.J.P.]

### THE LATENT IMAGE.

To the Editors.

Gentlemen,—I should be much obliged if you would give a few words of explanation of the reasons why the concavity of the lower part of the characteristic curve of the plate is assumed, in the note on page 42 of your Journal, to be strong evidence that the silver salt has a certain power of self-recovery from the strain imposed by light. I am much interested in this subject, having last year devoted a considerable amount of time to a study of the mathematical principles of these curves, and it has appeared to me that under any existing hypothesis of the action of light the curve must necessarily take a concave form at the lower end, except under one highly improbable condition—that is to say, accepting the assumption that each particle of silver haloid has a definite inertia becoming developable as soon as that is satisfied by the corresponding amount of exposure, the condition would be that the whole of the silver salt in the plate must have equal sensitiveness.

Under any other conditions it would also appear to follow that the upper part of the curve must become convex as a result of the exhaustion of the supply of unchanged haloid and the approach of maximum density quite apart from the influence of reversal.

Believing that a short statement of your views on the subject in question would have much interest for other readers besides myself, I have ventured to trouble you with this note.—Yours faithfully,

H. J. CHANNON.

20, Lewisham Hill, Lewisham, London, S.E.  
January 19, 1906.

To the Editors.

Gentlemen,—In reference to the paragraph in last week's issue, entitled "The Latent Image," it appears to me that that paragraph was written under a misapprehension. The characteristic curve of a plate is the D log. E curve. In the underneath portion this curve is strongly concave—in fact, it is logarithmic—for if the ordinates be converted into exposure units the under-exposed portion of the D log. E curve is a straight line (Hurter and Driffield, "J.S.C.I.," May, 1890). Now this is the ordinary photo-chemical law that work done is proportional to energy incident (Bunsen and Roscoe, "Photo-chemical Investigations"), and, in fact, for a plate coated with an emulsion, only one grain thick, the whole image is either under, or completely over-exposed, and there is no straight line portion. But when we deal with thick emulsions then the equation to the plate curve is given in terms of the absorption of active light by the upper layers of the film without any assumption as to the latent image whatever. (Hurter and Driffield, May, 1890). Four other equations for the plate curve of the same type have been deduced by Mr. H. M. Elder (Camera Club Conference, 1893), also without assumptions as to the latent image. Lastly, the collapse of the straight line into the over-exposed portion depends on the light having penetrated to the back of the film (i.e., having reduced the available bromide), and may be postponed indefinitely by simply increasing the thickness of coating. In fact, the length of the "straight line" is directly proportional to the capacity of the unexposed plate ("On the Sensitometry of Photographic Plates," "Phot. Journal," November, 1904).—Yours sincerely,

C. E. KENNETH MEES.

Ryeland, Caterham, Surrey.  
January 19, 1906.

[We are glad to see that our note has aroused the interest which has prompted the above letters, but we must explain that we hold no brief for any one of the theories relating to the latent image. The note in question was intended to be suggestive only.]

Mr. Mees' letter gives a clear and welcome explanation of the characteristic curve from the point of view of the theory originated by Messrs. Hurter and Driffield, and he explains the concavity of the lower part of the curve as a natural consequence of the Bunsen and Roscoe law. It has, however, been proved that this law fails with light of small intensity. Surely the failure of the law must be manifested in the curve, and in that case the curve must be affected by the phenomenon of self-recovery, to which phenomenon Dr. Bose attributes the failure of the law. On these grounds it appears to us that we were warranted in suggesting self-recovery as a factor to be considered in studying the concave portion of the curve.

As regards the convex portion, Mr. Mees states that the collapse of the straight line may be postponed indefinitely by increasing the thickness of the coating. In that case, when and where does reversal begin? We can hardly suppose that this is also postponed indefinitely in account of the thickness, and if it exists surely it must affect the curve in some way. We should like to ask Mr. Mees if the definite postponement of the convex curve has been proved by actual experiment, or whether it is a mere deduction from the equation to the plate curve. The fact that Messrs. Hurter and Driffield's formula fails to represent the effect of reversal was pointed out by Mr. H. M. Elder in the paper referred to by Mr. Mees.

Both our correspondents appear to place much faith in mathematical equations to the plate curve, but we may fairly ask how can reliable equations be arrived at until we possess considerably more knowledge of the actual mechanism of exposure and development. The most important attempt at analysis seems to be Mr. Sterry's solution of the curve into two curves ("Phot. Journal," February, 1904), one due to "primary development," and apparently fixed by exposure, and the other due to "secondary development," obeying no certain law, and varying with the chemical treatment of the plate. If we understand Mr. Sterry's experiments aright it appears that he found that the simple development of the exposure effect supplemented by an additional effect of the nature of intensification, more or less independent of the exposure effect. From these results it would appear that an equation designed to fit the compound curve is very possibly deceptive. The real effects of exposure may be effectually masked by the results of "secondary development."—S. B.J.P.]

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- J. Busby, 3, Avenham Terrace, Prestou, Lancashire. *Photograph of Declaration of Poll at Preston Election.*
- R. T. Ford, 125, King Street, Egremont, Cheshire. *Four Photographs of W. H. Lever, Esq.*
- H. J. Humphrey, Cravalls Road, Harpenden, Herts. *Photograph of St. John's Church, Harpenden.*
- Sarah Eddison, 2, Sheffield Road, Barnsley. *Photograph (Combination of Officials (Past and Present), Executive, Delegates, Auditors, and Office Staffs) of the Yorkshire Miners' Association, October 1, 1905.*
- Mary A. Frost, 24, Baxter Gate, Loughborough, Leicestershire. *Photograph of the old "Golden Fleece" and "General Hawcock" Public-houses, Loughborough, now pulled down and rebuilt.*
- Jakeman & Carver, High Town, Hereford. *Photograph of J. S. Arkwright, M.P.*
- W. H. Smith, c/o Fisher, Perry, Ltd., Dudley Street, Wolverhampton. *Photograph of Wolverhampton Technical School's 23rd Annual Soiree at Drill Hall, Wolverhampton, January 1, 1906.*

- Pinnock Bros., 48, Park Row, Bristol. *Two Photographs of the Rt. Hon. A. Birrell, K.C., M.P.*

### DRAWING REGISTERED:—

- W. Terry, 91, Evesham Street, Redditch. *Drawing of an Easter Postcard.*

COSWAY BORDERS STUDIO.—1. Will you kindly inform me where I can obtain masks for Conway printing? 2. Also the best method for using same to ensure correct register. 3. I propose to build another studio of following dimensions:—32 ft. long and 18 ft. wide. I shall be greatly obliged to you if you will give me full instructions as to the best way to build regarding the lighting, giving dimensions of glass on top and side, and positions of same, height of eaves from floor. Will not ground glass be the best, also should the side lights be perpendicular or slanting a little inwards? I might say the studio will be built on the top floor of a house, and has the following aspect, as shown in sketch.—URGENT.

1. From such houses as Marion's, Houghton's, and the like.
2. If you employ a printing-out paper there will be no difficulty with regard to registration, as you will see when the masks are in register.
3. We should advise that only the north-east side be glazed. About 6 ft. at either end, top and sides, may be opaque. The glass may be about 8 ft. at the eaves, starting, say, 2 ft. 6 in. from the floor. You will then be able to take the sitters at either end of the studio as occasion may require. It is quite a matter of taste whether ground or plain glass be used for the side. If the outlook is bad the former will be preferable. Bolas's book on Studio Construction will give you some useful hints. It is published by Marion and Co.

PUZZLED.—Winsor and Newton or Reeves and Co.

A QUESTION OF DAMAGES.—We sent some valuable cabinet portrait negatives to a postcard house for machine-printed postcards to be printed from them. They returned negatives so cut down in size that they will not trim a cabinet-size photograph. Have we any remedy for damage?—SUBSCRIBER.

The firm should certainly not have cut down the negatives without first asking your permission to do so. We think you might have cause of action for damages, but we question if you would recover much if you proceed. However, we think the

firm should make you some recompense if the negatives are reduced much below the usual cabinet size.

**BROMIDE TONING.**—Wishing to tone some prints to a red chalk tint I made up a copper sulphate, etc., bath from formula, on page 979 of ALMANAC, 1906, but without any result whatever. Must the prints be bleached (if so, please give formula) before immersion in the above solutions? There is no reference to it in that particular formula. Have had good sepia-tone results from soda sulphide, etc., toning, but require rather warmer tones. Your kind advice on a good working formula will greatly oblige.—A. T. A.

The formula is perfectly correct. You have evidently not made it up correctly; probably you have used ferrocyanide instead of ferricyanide of potassium. The use of the former would account for the inertness of the mixture. Why not try one or other of the ready-made toning preparations, such as those we reviewed a week or two ago?

**ARTIFICIAL LIGHT.**—Lights placed along the top of the background will be quite useless. They will obviously light the backs of the sitters. You will get a far better effect by placing the extra lamps alongside the present side light, but rather nearer the camera. Take care not to have your present side light too low down. From your sketch we should judge that you are not using a sufficiently large reflector behind your lights. An eight-foot frame, covered with white blotting-paper is not any too much. Do not have the reflector for the shadow side so much at the side, or you will get cross lighting. It should be brought much nearer to the camera. Your exposures, particularly with groups of three or four figures, will always be long with gaslight, and if you increase the number of lamps you get terrific heat.

**PYRO-SODA.**—Can you give me a pyro-soda developer that will give a good plucky negative with very rapid plates? I find great difficulty in getting sufficient density.—EN AVANT.

There is very little difference between pyro-soda developers. You should obtain what density you want by increasing the pyro up to, say, four grains per ounce. A developer very suitable for rapid plates is pyro-metol, and perhaps one of the formulæ for it in the ALMANAC would answer better with the plates you are using.

**NUMERO 13.**—Contrary to our custom to do as you request. Consult our advertisement pages.

**"VERITAS."**—Properly worked, there is no doubt the paper is permanent; equally so, and requiring the same care as ordinary C.C. paper. You should turn to the recent correspondence on the subject, and the article in our issue of November 10, 1905.

**A BOOK QUERY.**—Will be pleased to learn where I can obtain "Materia Photographica," or other work of the same nature, and as complete.—C. READER.

"Materia Photographica" is out of print. You might turn up a copy by inserting a small advertisement. There is no similar work in English.

**DRYING NEGATIVE.**—How, when I have developed and fixed a negative, can I dry it at once for immediate printing, the whole operation to take, say, 15 minutes. When I dry a negative quick with methylated spirit it turns white. I should like to know if this can be avoided? The keeping qualities of the negative are of no importance.—W. C.

Lay a piece of soft cambric upon the negative and evenly press it in contact with the film with a roller squeegee. A large proportion of the water will thus be removed, and the negative, if placed in a warm place will dry in a few minutes; with care, it can be held a short distance from a fire and can then be dried in as short a time as 15 minutes. Some plates will not stand this latter treatment without the gelatine running, and these you should place in a bath of formaline, 1 oz.; water, 10 oz.; for five minutes, and rinse in hot water, after which the negative can be dried at quite a considerable degree of heat in a very short time. The opalescence produced when you dry with spirit is due to the mineral naphtha in the latter.

**TROUBLED.**—Address the Tress Company (205, Oxford Street, W.), who, we believe, supply what you require.

**COLOURS FOR AEROGRAPH.**—Shall be much obliged if you will inform me through your paper this week where I can obtain the black and other water-colours, as used with the aerograph or any instrument for working up enlargements.—J. F. SLACK.

Reeves and Co.'s or Winsor and Newton's water-colours are the best for the purpose, and obtainable from any artists' dealer.

**STAND DEVELOPMENT.**—Kindly give a formula for stand development. Do you know of any book dealing with slow stand development?—A.C.S.

Almost any developer may be satisfactorily used for stand development except pyro, which is rather apt to stain the film. Glycin is particularly useful for this work, and the following is a good formula:—Sodium sulphite,  $2\frac{1}{2}$  oz.; hot water, 4 oz.; when dissolved, add glycin, 1 oz.; and then in small quantities add potassium carbonate, 5 oz. This forms a thick cream, and for use 1 oz. should be diluted with 80 ozs. of water and 8 grs. of potassium bromide added. This takes about two hours, so we prefer to reduce the amount of water to 60 ozs., which quickens its action. There is no English work on the subject, but Schmidt, of Berlin, has published "Das Stand-Entwickelung," by Dr. Blech. Two or three formulæ are given in the 1906 Almanac.

**BRIXTON.**—We should choose No. 1 or 2. No, we cannot recommend anything cheaper; if you want quality you must pay for it.

**F.D.**—You could use any in your list; possibly we should choose No. 2 or 3.

**BROMIDE PAPER.**—1. Can you give me any reliable preventative for surface markings in bromide paper and postcards, particularly glossy? 2. I am building a new dark room for enlarging purposes, and have a choice of two positions. One will give me fairly even daylight only, artificial in this case is out of the question, owing to distance same will have to be brought, being at the top of building. The other will be useful for artificial light only. With daylight I find I can use an old camera for enlarging. If I decide on artificial light can I still use this camera, or would it be necessary to have a lantern? I am of course referring to obtaining the best results, and as I should in either case use the same lens, cannot see why my present instrument will not serve. 3. For artificial light, is a condenser necessary? if so, should I be right in making a tin lined box for arc lamp, with condenser in front of box, then camera back made to fit in front of condenser.—"BROMIDE."

1. We know personally of no reliable preventative, but a correspondent in our issue for December 22, 1905, stated that the addition of a few drops of methylated spirit to the developer would have this effect. 2. Which is the better of the two methods is to a great extent a matter of opinion; but for professional work we should advise artificial light, as always being available and more constant. There would be no difficulty in using the old camera for artificial light, if it can be used for daylight. 3. A condenser is not absolutely essential, but as it condenses the light it obviously means shorter exposures, and this might be a consideration. The arrangement of light, box, and camera would be correct.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The event of the week in photographic circles is the opening on Tuesday next of a one-man show at the Royal Photographic Society, Alvin Langdon Coburn. We give a portrait of Mr. Coburn and an account of his methods, and are also able to publish a very characteristic appreciation of his photography by Mr. G. Bernard Shaw. (P. 85.)

Colour Photography.—A further description of the "Drac" method obtaining the three colour-sensation negatives without filters by fitting the image from one lens into a spectrum is published, with an account of the practical performance of the process. (P. 87.)

Colour Photography.—An American inventor has put forward a process of colour photography, the results of which, it is naively timed, will always be "true to some phase of nature," and may be very pleasing to the worker intended. The method appears to be a combination of ferro-prussiate and gum-bichromate produced on a support of coloured paper. (P. 88.)

Colour Photography.—To-day and every weekday from 10.30 to 4.30 (Tuesdays, 10.30 to 12.30) an exhibition of colour photography is open to the public at the offices of "The British Journal of Photography."

In continuing a criticism of the proposed alterations in the copyright law it is pointed out that many portions of the bill are incapable of intelligible interpretation. The clause relating to the marking of plates, if it means what it may be construed to mean, would have the effect of destroying largely the photographer's rights in his photographs. (P. 83.)

The method of print-out gum-bichromate by an indirect process the subject of some notes by Mr. E. W. Foxlee in continuation of the report of the demonstration in our last issue. (P. 89.)

A method of making self-toning paper has been patented in which cyanide is added to an emulsion containing gold chloride and silver hydrocyanide. It is claimed for it that treatment in a salt or water bath gives a fixed tone independently of the time of action. (P. 92.)

It has been found by E. J. Wall that the new "Sanzol" reducer is well adapted for prints on P.O.P. and bromide papers, and that it is itself a species of local reduction by friction. (P. 80.)

## EX CATHEDRA.

**The Congress of Applied Chemistry.** The meeting of this annual congress to be held in Rome from April 26 to May 3 is now preliminarily arranged, and a lengthy circular of the officials and programmes in the various sections has been published. Section IX., photography and photo-chemistry, meets under the presidency of Colonel Pizzighelli, and so far is able to announce only two items on its agenda, two papers by a Russian. The one is "Notes on Processes of Photography in Natural Colours," and the second, "Applied Photography in Russia," both by S. De. Prokondine-Gorsky, St. Petersburg. We understand that offers of papers may still be made to Colonel Pizzighelli, and he will answer enquiries to him as to the general arrangements of the congress, or place them in the proper hands. We also hear that there is some prospect of the Congress, which is looked upon as an important one in chemical circles, assembling in London next year. Hitherto its meetings have always been held in Continental centres.

## Colour Contrast.

The ordinary use of the orthochromatic plate with the "yellow screen," as it is commonly called, is to render the luminosities of various coloured objects with approximate accuracy in monochrome. The ordinary plate gives blues too light and yellows too dark. The orthochromatic plate and light filter will correct this error. But it may occur that the design on a fabric or vessel, or the inlaid work on a piece of furniture, is not sufficiently emphasised when the relative luminosities are fairly accurately rendered. Recourse may then be had to the well-known method of emphasising the colour contrast. Suppose the article to be a satin-wood table decorated with painting in a greenish shade, quite an everyday example. The decoration shows distinctly to the eye by reason of the difference between yellow and green—that is, by the contrast of colour. But if it happens that the luminosity of the green is almost or quite the same as that of the yellow the orthochromatic plate and yellow screen will give a negative showing little or no contrast between the wood and the decoration. An ordinary plate may quite conceivably render the green actually lighter than the yellow satin-wood, particularly if the green be of a bluish shade. In order to get the green decoration darker, a light-filter would be used of a colour almost a complementary to green, say deep orange, but care should be taken not to go too far, or the green would be translated as black. If a perfect complementary to green—that is, red—were employed such would be the effect. In the case of a vase with a design thereon in red the red may be made lighter in the monochrome rendering, by using the orthochromatic plate with a red light-filter, or the red may be made darker

by using a green light-filter. By using various suitable dyes in a cell composed of two sheets of thin plate glass, these special contrast light-filters may readily be prepared. Such a cell may be purchased for a few shillings only, and two or three experiments will convince the photographer of the importance of the subject when dealing with many branches of technical work.

\* \* \*

#### **Photographing Furniture.**

We referred several weeks ago to the difficulty of photographing brightly-polished furniture on account of the excessive contrast between dark-red woods and the reflection of white light from the polished surface, pointing out the advantage of such work being done before the polishing was accomplished. We have recently had inquiries as to the best method of handling such work, the principal difficulty encountered being the loss of the figuring of the wood and the incorrect colour-rendering of inlaid work. Where pieces of furniture are both inlaid and highly polished the worker is face to face with the difficulty that he needs to emphasise slightly the contrast between the wood and the inlay, and at the same time he needs to diminish the contrast between the wood in shadow and the bright reflections. The only satisfactory method of working is to use as much light as possible, and that a very diffused light. In this way the general illumination of the article is good, and there is an absence of strong shadow. At the same time, the light being very soft, the reflections are much less brilliant. Probably the open air on a grey day would give the most favourable conditions. With regard to the rendering of contrast between, say, the mahogany and the satin-wood banding, usually met with in Sheraton furniture, an orthochromatic plate sensitive to yellow, or orange-yellow, should give a satisfactory result. The light-filter employed would need to be something different from the three- or six-times screen commonly met with. We should suggest a fairly deep screen, say, a gelatine film dyed with tartrazin or brilliant yellow till it increased the exposure at least twenty times.

#### **Questionable Advertising.**

A New York photographer is credited with inventing a novel advertising scheme which is said to have brought him much business. The object of his attentions, if a lady, receives a portrait of an attractive looking girl with no other inscription on it than "To Elizabeth from Eugenia" (Elizabeth being the Christian name of the recipient ascertained from the directory) and the photographer's name and address printed on the mount in the usual way. Feminine curiosity prompts the lady to solve the mystery of the unknown Eugenia by visiting the photographer, who professes with every assumption of truth that the portrait is that of a Miss Eugenia Reynolds, who at the time of the sitting was resident in such and such a street: the subject of the portrait being actually a model engaged by the photographer for the purpose of his little ruse. The visit to the studio is made the opportunity to bring the photographer's work before the fair prospective client, but we can well understand the need of an editorial caution which accompanies our contemporary's account of this advertising method.

\* \* \*

#### **Some Optical Illusions.**

While attempting to read the election results as they were spelt out in the "dashed dottey" system of Mr. Morse, we noticed two interesting illusions. So long as the gaze was directed to the search light it was impossible to get away from the idea that at the commencement of each

flash the light emerged from the lens like a jet of water from a hose, and that it receded back into the apparatus at the end of the flash. The cause of this illusion is doubtless the fact that the brightest part of the beam next the apparatus affects the retina most, and is the first part that we perceive and the last that we lose sight of. The next illusion, however, does not permit of any similar easy explanation. We found that the eyes were less worried by the flashes, and the distinction between the dots and dashes was better perceived, when we looked away from the flash, so that the image fell on the side of the retina. The illusion just described then disappeared, but instead of an apparent longitudinal movement of the beam we perceived a transverse or vertical one. At the commencement of each "dash" the beam appeared to rise parallel to itself, while it fell at the end of the dash. The rising effect was very marked indeed, but the falling effect was less obvious, and we did not in all cases perceive it. We have at present no satisfactory explanation to offer of this, but perhaps readers with a taste for optical matters will like to worry it out. The inclination of the searchlight was about 15 deg. from the horizontal, while the angular deviation of the eye away from the light was, perhaps, 50 deg. This brought the image on to the nasal side of the retina, and the direction of the inverted retinal image of the flash must have been towards the front of the eye.

#### **Studio Lenses.**

A few days ago a photographer brought to us a second-hand portrait lens of about eight inches focal length, to ask if it was useful for cabinet work in his studio. He also wanted to know whether we should advise him to buy an 8 in. anastigmat with large aperture to use when more depth of focus was necessary. As there are no doubt others who are in some uncertainty as to the most suitable lens for certain work, we may refer to the salient points in selecting an objective for studio work. Where the studio is short, the focal length of the lens must not be too great if half and three-quarter length portraits are to be produced. Eight inches is about the shortest focus we should use for three-quarter length cabinets, and some care would be necessary in posing to avoid violent perspective. It is, of course, much too short a focus for cabinet heads. As we presume both classes of portraits are done in almost every studio, it becomes necessary to have a second lens of longer focus if the short length of the studio demands an 8 in. objective for the three-quarter length pictures. For good perspective or "drawing," 15 in. is not any too much for heads of about 2 in. It is difficult to get people to understand that an anastigmat lens at  $f/4.5$  has no more depth of focus than a portrait lens at the same aperture, and it should be remembered that though many Petzval lenses are marked  $f/4$ , they are most usually only nominally of that aperture, and really of a somewhat smaller one. Where the anastigmat lens scores, however, is in its flatness of field. Every user of the portrait lens knows that when taking a standing figure it is difficult, if not impossible, to get reasonably good definition in the central part of the picture at the same time that the head and feet or knees of the subject are in focus. This arises from the curvature of field of the Petzval type of lens. With the anastigmat, or flat field lens, the definition is uniform over the whole of the figure.

\* \* \*

#### **The Lens for Groups.**

Where much group work is anticipated in the studio the anastigmat is again the lens to select. The portrait lens, with its roundness of

eld, may be utilised, the defect being met by arranging the figures in a crescent. The definition on the margins will still be unsatisfactory, however, by reason of the astigmatism present in the lens. Stopping down improves the marginal definition, but prolongs the exposure at the very time when the risk of spoiling the plate by movement is increased through the inclusion in the picture of several figures instead of one. The modern anastigmat enables the group to be arranged fairly in one plane, and, this being done, gives as fine definition for the outside figures as for those in the centre. Our advice, then, regarding the purchase of lenses would be to obtain an anastigmat of eight, nine, or ten inches focus, according to the length of the studio, and working at an aperture of at least  $f/6$  or  $f/5.6$ . Such a lens would answer admirably for producing full length, three-quarter length, and group pictures. In addition to this, it would, of course, be useful for outdoor photography, and an ideal lens for enlarging purposes. The selection of the second lens for large cabinet heads would depend on circumstances. If any quantity of Imperials or 12 by 10 portraits were done, the lens should be of a size and quality suitable to their production. This would mean another anastigmat of 15 in. focus in the case of Imperials, and 18 to 20 in. for 12 by 10 work. For all-round cabinet heads in an average studio we should prefer the lens of 15 in. focus. If large work had not to be prepared for a good second-hand portrait lens of 14 to 16 in. focus might be picked up. Lenses of very excellent capabilities may frequently be obtained for a few pounds, but care should be taken to see that the lenses themselves are not abraded by constant "polishing" with any odd piece of cloth. One or two distinct scratches are of much less import than a dulness of surface caused by myriads of tiny scratches.

#### PROPOSED ALTERATIONS IN THE COPYRIGHT LAW.

IN our previous article it was shown that the proposed Bill of the Artistic Copyright Society is calculated to provide ample opportunity for the employment of the legal fraternity in unravelling its mysteries, and we must now return to the subject and expose other ambiguities, and show also that the Bill makes an unfair and inequitable distinction between photographs and other forms of graphic art.

The distinctive treatment of various classes of work in the proposed Bill involves definitions, and definitions are pitfalls even for the most skilful in the use of language, legal and otherwise. There is first the broad division into works of fine art, original works of fine art, and other works; then there are definitions of various classes of work—painting or drawing, sculpture, engraving, photograph, and casts from nature—and the Bill still further contemplates, in some connection, a work of fine art made by one person from a work of fine art designed by another, though it is notable that it does not contemplate a work of fine art made by one person from a work not of fine art, e.g., a photograph, made by another, and, considering the number of paintings that are made from photographs, it is a class that surely should be recognised. With such a number of classes the difficulties of steering clear of latent contradictions are of course enormous, even where the definitions themselves are comprehensive and conclusive. That of a photograph is certainly the least so of any.

It will be noticed that in the definition of engraving and cast from nature that not only is the plate and the

mould made the subject of copyright, but also the impression and the cast. The definition of photograph, either intentionally or accidentally, omits to include the print or impression, and accordingly under the definition a photograph is not a photograph unless it permits of prints or copies being taken or multiplied definitely or indefinitely. A daguerreotype or ferrotype is therefore not a photograph, and no copyright can exist with regard to it, and this applies to a photograph of any kind which is complete in itself, including all prints produced by processes of pure photography, and impressions from photographic plates and process blocks.

But let us assume that the definition is to be made consistent, and consider the conditions imposed on the photographer for the maintenance of his copyright. We have to refer again to Section 22 and its sub-sections. We have shown that Sub-section A breaks down at once on application, that literally it may enjoin a statement contrary to fact, and that there is nothing in the context to show what was otherwise intended. Sub-section B is rather more than less a muddle. It provides for the marking of copies with the name of the proprietor of the copyright, but similar confusion arises. For instance, in the case of a photographic copy of an engraving from a painting. Here there may be three proprietors of copyright. Literally, the proprietor of the copyright in the engraving is the proprietor indicated and the year of completion of his work; but probably the proprietor of the copyright in the photograph was really intended. We have pointed out that under the definition of a photograph a photograph must be capable of producing prints or copies, the word copies clearly being used as practically synonymous with prints. A negative answers the definition of a photograph, and in applying the sub-section the opening words, "In the case of a reproduction of any other work," if taken in one sense, distinctly imply, in the case of an ordinary photograph, "In the case of the reproduction of a negative." A print is emphatically not a reproduction of a negative, therefore the sub-section cannot apply. The alternative meaning of "reproduction" is as the word is used in Sub-section A, as a synonym of "copy," the substantive of the verb to copy in the sense the verb is used in Section 2. In that case, again, the sub-section would not apply to photographs of views, persons, or objects, for the term "any other work" is clearly inapplicable to such subjects. The word "work" can only apply to a human performance, and a photographic view is emphatically not a reproduction of a work.

The section, as a whole, is one of the most extraordinary examples of ungrammatical and slipshod language to be met with in an Act of Parliament or elsewhere. "He" is used as the pronoun referring to "persons." The word "copies" is used indiscriminately to mean multiplied representations of works the subject of copyright, prints or impressions from plates, negatives or blocks, and also as the plural of the substantive of the verb to copy as used in Section 2. "Work" apparently is used indeterminably to mean the work from which a photograph, say, is produced and the production itself. Reproduction means in one place copy as the substantive of "to copy," and in another apparently merely a print or impression. Without explanation the section is simply nonsense.

But as the subject matter of this portion of the Bill is such an important one to photographers and it is impossible to discuss the effects of the proposed alteration in the law of copyright without an understanding of what the conditions to be imposed are, we shall make a guess at what the section really is intended to mean.

"Before delivery for sale, etc., of any copies made by any means, or multiplications of the design or subject

matter by any method or process of any work the subject of copyright, or of any prints, impressions, or casts of any negative, plate, block, mould, or matrix the subject of copyright, such copies, multiplications, prints, etc., shall be marked:—

"(a) When the design or subject matter of an original work of fine art is copied or multiplied," so and so. We confess we cannot fathom what was intended.

"(b) In all other cases each copy, multiplication, or print shall be marked with the name of the proprietor of the copyright in the negative, plate, block, mould, or matrix, together with the word copyright and the date of the year in which the period of copyright commenced and in default of such marking," etc.

This is not what we think the law ought to be. It is merely the sense we believe the drafters of the Bill intended to convey, and we do not profess that our drafting of their intentions is flawless. We give it in order to discuss its effect upon photographers.

Under the existing Act, copyright in a photograph remains with the original proprietor until he chooses to assign it, or until he disposes of the negative, when, if no agreement is made in writing as to whether it shall be transferred or remain in his possession, it ceases to exist. But he cannot exercise his full rights unless he registers it. The system works very well; but it does not suit the profler after free illustrations. Anyone who may happen to consider a photograph which comes into his possession a desirable property to be exploited for his own benefit is under the disability that in parting with the print the proprietor of the copyright has not therefore parted with his sole right to reproduce it. The essence of copyright justice is that the originator of any work in which a right of reproduction is involved—not necessarily the author, as the drafters of the Bill we are discussing seem to have imagined—is entitled to the benefit of the work, and the right to assign his interest. But a copyright is an abstract and not a tangible property, which the owner may or may not attach value to, and there must be some limit imposed as to its continuance to be settled in an arbitrary way, but in accordance with some primitive principle tempered with expediency. At present the natural determination of a copyright is based upon the author's lifetime, a perfectly equitable arrangement were the author necessarily the interested party; but the author in many cases has not, and sometimes never had, an interest in the copyright, and a fixed term is therefore more in accordance with general policy, besides avoiding the speculative nature of property in copyright which now obtains. In this respect the Bill partly rectifies the existing system. Expediency dictates that the owner of a copyright shall signify in some way whether he reserves his rights for his sole use, otherwise it is to be assumed that anyone is at liberty to make use of his work without hindrance. How this signification shall be given must form part of a Copyright Act, and it is a matter not to be lightly treated. To prescribe a method which involves much time, trouble, or expense is practically to restrict the enjoyment of copyright in a way contrary to the spirit of copyright legislation, and if our idea of the intention of the Bill is correct, the conditions to be imposed upon photographers are of such a nature that in very many cases they cannot practically be complied with. If Section 22 means that if any one copy of a photograph be issued without the prescribed marking the owner is deprived of all remedy for infringement, there will not be any copyright in the majority of photographs, and in the case of portraits, the only remedy against pirates will be under common law, as naturally photographers will not put themselves to the trouble of marking their customers' portraits as prescribed.

A further hardship on photographers is the condition precedent to the right of action and the recovery of penalties that the proprietor of a copyright shall show that he took proper steps to secure the marking of all copies issued by him. In the case of an engraving, or photographure, or block, no difficulty would arise; the fact that the required mark appeared on the plate would be sufficient evidence; but when prints are marked individually by a stamp or otherwise, to prove that no print escaped would be an impossible task. The false marking of a print is made a punishable offence, but the removal of the mark is not provided against; hence, if the marking on a photograph be trimmed off the photographer has no remedy against the individual who may have trimmed off his mark, and so caused him infinite trouble in proving that he was entitled to the protection of the Act.

We have mentioned that the Bill alters the term of copyright. In the case of a photograph it provides that it shall exist for thirty years after the end of the year in which it was completed (Section 3), and it is further provided that the copyright in existing works shall endure for the term provided in the new enactment, or that of the present Act, whichever is the longer.

Section 5 of the Bill provides that when the subject of a work is a portrait, and is made for payment, the original proprietor of the copyright shall be the person at whose instance the work is made, but the wording of the sub-section expressly excludes the application of this proviso to a group. Section 9 deals specifically with the original proprietorship in photographs. It states that in the case of a person who employs another person to do the work, and who gives pecuniary consideration for the work, the employer shall be considered the author. It is not clear whether this is intended to mean that anyone who employs a photographer becomes proprietor of the copyright in the photograph, or whether the expression "who employs another person" is intended to apply only to employment in the connection of employer and servant. If the former, the relationship of photographer and sitter in relation to the copyright of the photograph is left as at present.

Section 6 materially alters the existing law. At present on the sale of a work, or of the negative of a photograph, the copyright ceases to exist unless an agreement is made reserving the copyright to the seller or transferring it to the buyer. The Bill provides that the copyright shall remain with the seller unless expressly assigned to the buyer.

We have treated at length the marking of photographs that is imposed, but we have not mentioned that as far as photographs are concerned there will be no such thing as registration. Section 23 (Sub-section 2) of the Bill provides that the regulations as to marking shall apply to existing works, but as Sub-section 4 provides that nothing in the section shall diminish any subsisting rights, it is far from clear what is intended.

We have treated the subject of the proposed Bill at considerable length, not because we think the modification of copyright law is likely to come within the range of practical politics in the near future, or because we suppose that the Bill in its present state will ever be presented to Parliament, but because it is well that photographers should be aware that there are influences at work, to say the least, not friendly in disposition towards their interests. We have condemned the Bill in explicit terms. The drafting of a Bill is difficult under any circumstances, but if in this case an honest attempt had been made to deal with all interested in an equitable way, most of the difficulties would never have occurred.

## ALVIN LANGDON COBURN.

For several years photography has been in the throes of an upheaval. This renaissance has affected alike the professional and the amateur, though it is chiefly the efforts of the latter which have been noticed—on account of the amateur's greater pliability. The movement has not been confined to this country; it has been in force on the Continent, and particularly in America. In this latter country it has been marked by bitter controversy, not a few echoes of which have rumbled across our shores. Meanwhile, discerning people have welcomed the movement, and, while smiling at each that has been offered to them, have earnestly commended the same—and have awaited developments. One thing is sure—that photography has been so taken up that the inevitable result is a step forward; it has been led from a rut to which it can never return.

Several interesting collections of American work have been seen in this country, sometimes containing pictures by many makers, and at other times "one-man shows." One of the latter will be held on Tuesday next in the rooms of the Royal Photographic Society, 66, Russell Square, W.C., and will remain open until the end of March. The pictures shown are by Alvin Langdon Coburn, one of the youngest of American workers. Though he is a hard worker in the literal sense of the word, he would probably speak of himself as a student. Like so many well-known photographers, he has drifted into the work. He has been practising assiduously for fifteen years—began when he wrote a page with one figure—he is still practising. For years photography was to him merely an enthusiastic hobby, and it was not until a widening circle of friends and admirers asked for his pictures that he was compelled in self-defence, and probably with a view of choking them off, to put a price on them.

There are two broad classes into which photographic workers of the new school naturally fall; one class which is, unfortunately, much in evidence, includes those who look to photography as a quick step to superficial success, and who, taking advantage of the fatal facility of the camera, appeal to the public at a stage when they ought to be studying in private.

The other class is that which has mastered the technique of the work, and out of considerable knowledge can select the means of expression most suitable for its needs at the moment. Mr. Coburn belongs to the latter class; he at least does not shirk work, and may be said to have voluntarily gone through, and to be still going through, the mill. As long as he considers himself a student he is in the right way to strengthen his already strong work.

He appears to have a sane appreciation of the limitations

and the possibilities of his art. He can see the picture which is everywhere latent, and wait until conditions are favourable to translate it according to his vision of it; but in congenial surroundings he is quite capable of exposing as many plates in the course of a day as the average enthusiast can. The exposures are not made at haphazard—it simply means that he has the facility of quickly choosing the best view point, and of getting his picture without any fumbling delays.

We are not in this article either describing or criticising the work which is hung; reference will be made to it in a later issue, to which we refer our readers, and we urge all who possibly can to see the exhibits themselves. Perhaps if there were fewer pictures to be hung they could be seen with less effort; as it is, it is not a collection to be dealt with in an idle quarter of an hour. The man who would seriously examine them must either confine his attention to a few of them, or visit the exhibition more than once. One of the most noticeable traits in Mr. Coburn is his wide catholicity of

Photograph by]

ALVIN LANGDON COBURN.

[Reginald Craigie.

choice; it may be a view of a London fog requiring ten minutes' exposure at noon, or it may be a sunlit snowscape—whichever it is, he sees the picture and the proper handling of it.

In portraiture—that most difficult branch of work—Mr. Coburn's pictures have received the hall mark of competent judges. A somewhat lengthy series of portraits of British notabilities, literary and artistic, has been given in supplement form in several issues of the "Century Magazine." Needless to say, he does not usually go for the sharp-focus picture; his first aims in portraiture are character and personality. We believe he is not very favourably inclined to the usual methods of professional lighting; if he equipped a studio

probably the skylight would be conspicuously absent. In practice he takes his pictures where his sitters happen to be; some of his best portraits have been taken in the open air, sometimes under the sky only, at other times under a tree. Instead of moulding his sitters to the conventions of his art, he uses art to express his sitters naturally.

His favourite workroom is an ordinary living-room, usually with all the windows except one blocked, and half the light of that one, perhaps stopped out. A circular folding fan reflector of white cotton, about 40 in. in diameter, and a metal socket which, when clamped to a chair, holds the reflector, are his only apparatus besides the camera. Mr. Coburn has a lens for every occasion; his battery includes

a number of experimental lenses which have been made specially for him by an American friend—Mr. Henry Smith, of Boston—and some of which have never been put on the market.

Mr. Coburn is making a long visit to Europe, more with a view to study than to the making of professional work, and the exhibition is an incident in response to the request of a number of friends. He has worked much on the Continent, and is now in London—a city that he has fallen in love with—learning photogravure and other branches of photography and allied work which he considers necessary to make him master of his craft.

## GEORGE BERNARD SHAW ON COBURN'S PHOTOGRAPHY.

THE catalogue of the exhibition of Mr. Coburn's photographs contains the following appreciation from the pen of Mr. G. Bernard Shaw.

Mr. Alvin Langdon Coburn is one of the most accomplished and sensitive artist-photographers now living. This seems impossible at his age—twenty-three; but as he began at eight, he has fifteen years' technical experience behind him. Hence, no doubt, his remarkable command of the one really difficult technical process in photography—printing. Technically, good negatives are more often the result of the survival of the fittest than of special creation: the photographer is like the cod which produces a million eggs in order that one may reach maturity. The ingenuities of development which are so firmly believed in by old hands who still use slow "ordinary" plates, and develop them in light enough to fog a modern fast colour-sensitive plate in half a second, do not seem to produce any better results than the newer timing system which is becoming compulsory now that plates are panchromatic and dark rooms must be really dark. The latitude of modern plates and films, especially those with fast emulsions superimposed on slow ones, may account partly for the way in which workers like Mr. Evans get bright windows and dark corners on the same plate without over-exposure in the one or under-exposure in the other. And as to choosing the picture, that is not a manipulative accomplishment at all. It can be done by a person with the right gift at the first snapshot as well as at the last contribution to The Salon by a veteran. But printing remains the test of the genuine expert.

Very few photographers excel in more than one process. Among our best men, the elder use platinotype almost exclusively for exhibition work. People who cannot see the artistic qualities of Mr. Evans' work say that he is "simply" an extraordinarily skilful platinotype printer, and that anybody's negatives would make artistic pictures if he printed them. The people who say this have never tried (I have); but there is no doubt about the excellence of the printing. Mr. Horsley Hinton not only excels in straightforward platinotype printing, but practises dark dexterities of combination printing, putting the Jungfrau into your back garden without effort, and being able, in fact, to do anything with his methods except explain them intelligibly to his envious disciples. The younger men are gum-mists, and are reviled as "splodgers" by the generation which cannot work the gum process.

But Mr. Coburn uses and adapts both processes with an instinctive skill and range of effect which makes even expert photographers, after a few wrong guesses, prefer to ascertain how his prints are made by the humble and obvious method of asking him. The device of imposing a gum print on a platinotype—a device which has puzzled many critics, and which was originally proposed as a means of subduing contrast (for which, I am told, it is of no use)—was seized on by Mr. Coburn as a means of getting a golden brown tone, quite foreign to pure or chemically toned platinotype, whilst preserving the feathery delicacy of the platinotype image. Lately, having condescended to oil painting as a subsidiary study, he has produced some photographic portraits of remarkable force, solidity, and richness of colour, by multiple printing in gum. Yet it is not safe to count on his processes being complicated. Some of his finest prints

are simple bromide enlargements, though they do not look in the least like anybody else's enlargements. In short, Mr. Coburn gets what he wants one way or another. If he sees a certain quality in photogravure which conveys what he wants, he naively sets to work to make a photogravure exactly as a schoolboy with a Kodak might set to work with a shilling packet of P.O.P. He improvises variations on the three-colour process with casual pigments and a single negative taken on an ordinary plate. If he were examined by the City and Guilds Institute, and based his answers on his own practice, he would probably be removed from the class-room to a lunatic asylum. It is his results that place him "hors concours."

But, after all, the decisive quality in a photographer is the faculty of seeing certain things and being tempted by them. Any man who makes photography the business of his life can acquire technique enough to do anything he really wants to do: where there's a will there's a way. It is Mr. Coburn's vision and susceptibility that make him interesting, and make his fingers clever. Look at his portrait of Mr. Gilbert Chesterton, for example! "Call that technique? Why, the head is not even on the plate. The delineation is so blunt that the lens must have been the bottom knocked out of a tumbler, and the exposure was too long for a vigorous image." All this is quite true; but just look at Mr. Chesterton himself! He is our Quinbus Flestrin, the young Man Mountain, a large, abounding, gigantically cherubic person who is not only large in body and mind beyond all decency, but seems to be growing larger as you look at him—"swelling visibly," as Tony Weller puts it. Mr. Coburn has represented him as swelling off the plate in the very act of being photographed, and blurring his own outlines in the process. Also, he has caught the Chestertonian resemblance to Balzac, and unconsciously handled his subject as Rodin handled Balzac. You may call the placing of the head on the plate wrong, the focussing wrong, the exposure wrong, if you like, but Chesterton is right, and a right impression of Chesterton is what Mr. Coburn was driving at. If you consider that result merely a lucky blunder, look at the portrait of Mr. Bernard Partridge! There is no lack of vigour in that image: it is deliberately weighted by comparative under-exposure (or its equivalent in under-development), and the result is a powerfully characteristic likeness. Look again at the profile portrait of myself "en penseur," a mere strip of my head. Here the exposure is precisely right, and the definition exquisite without the least hardness. These three portraits were all taken with the same lens in the same camera, under similar circumstances. But there is no reduction of three different subjects to a common technical denominator, as there would have been if Franz Hals had painted them. It is the technique that has been adapted to the subject. With the same batch of films, the same lens, the same camera, the same developer, Mr. Coburn can handle you as Bellini handled everybody; as Hals handled everybody; as Gainsborough handled everybody; or as Holbein handled everybody, according to his vision of you. He is free of that clumsy tool—the human hand—which will always go its own single way and no other. And he takes full advantage of his freedom instead of contenting himself, like most photographers, with a formula that becomes almost as tiresome and mechanical as manual work with brush or crayon.

In landscape he shews the same power. He is not seduced by the picturesque, which is pretty cheap in photography and very tempting. He drives at the poetic, and invariably seizes something that engages you into a mood, whether it is a mass of cloud brooding over a river, or a great lump of a warehouse in a dirty street. There is nothing morbid in his choices. The mood chosen is often quite a holiday one; only not exactly a Bank Holiday: rather the mood that comes in the day's work of a man who is really a free worker and not a commercial slave. But anyhow, his impulse is always to convey

a mood and not to impart local information, or to supply pretty views and striking sunsets. This is done without any impoverishment or artification. You are never worried with that infuriating academicism which already barnacles photography so thickly—selection of planes of sharpness, conventions of composition, suppression of detail, and so on. Mr. Coburn goes straight over all that to his mark, and does not make difficulties until he meets them, being, like most joyous souls, in no hurry to bid the devil good-morning. And so, good luck to him, and to all artists of his stamp. G. B. S.

## COLOUR PHOTOGRAPHY.

THE Exhibition of examples of Colour Photography, at present open at our offices, continues to be visited daily by some fifty or sixty people to whom the collection apparently is the source of considerable interest and pleasure. To the notices by the daily Press, which we quoted last week, we could add a number of others from weekly technical and other journals, but calls upon our space in the present issue compel us to postpone further reference of this kind until a more convenient occasion. The exhibition has made us the recipients of a number of communications bearing on Colour Photography, all of which we hope to present to our readers during the next few weeks. Several notices of newcomers in colour photographic processes, claiming the attention of the reader are dealt with below, and in future issues we shall publish among other items practical articles on the making of three-colour prints by the carbon process, on three-colour the "Sinop" colotype process, and on some new apparatus designed to provide the photographer with the opportunity of making his first excursions into colour photography.

### COLOUR PHOTOGRAPHY WITHOUT FILTERS AT ONE EXPOSURE.

In our issue of January 12 we published a few notes on the new method of colour photography without filters invented by Mr. C. J. Drac, of Warsaw. After witnessing the working of the apparatus at the Photographic School at the Polytechnic, Regent Street, W., where Mr. Drac has taken a number of photographs of various objects, including portraits from life, we can give our readers some further particulars of this method which should certainly interest workers in colour photography, inasmuch as it approaches the problem of making the colour records in an entirely novel way.

Coloured light-filters of one sort or another have been invariably employed in analytic methods of colour photography since the time of publication of Du Hauron's papers in 1869. Joly made them narrow bands; the Lumières propose to distribute them as fine powder; Mr. Drac dispenses with them altogether. In their place he uses a system of spectral analysis, and in part of his apparatus does any coloured filter occur. He does not claim the discovery of any new principle in heliometry. He has worked out his system in conformation with established and acknowledged theories of Young—that is to say, he aims to carry out the following conditions:—

(a) The three colour-sensations into which the multi-coloured image is divided—i.e., red-orange, green, and blue—must be complementary to each other.

(b) The blue, purple, and yellow dyes by which an actual picture is produced must also be complementary between each other.

(c) The following pairs must be complementary colours:—(a) The red-orange colour-sensation, and the blue print-colour; (b) the green colour-sensation and the purple printing colour; and (c) the blue-violet sensation and the yellow printing colour.

As everyone knows, the state of our knowledge of dyes and pigments does not enable us to produce permanent colours of arbitrary spectral composition, and hence the theoretical conditions cannot be satisfied in practice. This disparity, and the additional difficulties caused by the unequal time of exposure for the single colours, and by the action of the ultra-violet rays, have convinced Mr. Drac that correct colour photography means of filters is more an art and a craft, dependent for results upon the personal choice of the worker, than a technical operation following a fixed method. Adopting the

three-colour principle as derived from Young's theory of vision, Mr. Drac circumvents the difficulties of filters by transferring the problem from chemistry to optics. The three sets of rays which produce the negatives in the "Drac" apparatus, according to the above mentioned conditions, are strictly complementary, as they are produced by dividing an actual spectrum. Such a system of dissection of the spectrum permits of the adjustment of the composition and strength of each section to the sensitiveness of the plate so as to obtain the same time of exposure for all three negatives. This adjustment once made, the action of the apparatus depends upon its geometrical construction, and the uniformity of the results is further ensured by the elimination of the ultra-violet rays by means of a screen suitably placed at the limit of the visible spectrum. The apparatus is employed both for the making of the colour-sensation negatives and for the viewing or projection of colour records by additive synthesis. For the latter purpose the positive transparency from the triple negative is placed in the position occupied by the plate, and thus a system of direct colour photography is available in which no coloured means of any kind are used. A number of results shown to us at the Polytechnic were most excellent reproductions of the colour, texture, and lustre of the originals. The time of the exposures varies from half a second to two seconds, and in bright sunshine, Mr. Drac tells us, he has obtained the whole exposure in one fifteenth of a second, although the only apparatus yet at his disposal has been a working model.

In regard to the employment of the negatives for photographic and photo-mechanical printing by subtractive synthesis, there is still the disability of the want of coincidence of inks and pigments with theoretical requirements, but the "Drac" apparatus can be applied to the adjustment of the printing colour, with a view to making it as closely as possible the complementary of the rays by which the negative was taken. The device is a simple one. It was used by Mr. Ives years ago, and has been demonstrated not long ago by Messrs. Newton and Bull, at an R.P.S. meeting. The "Drac" apparatus easily permits the complementary colour to be obtained in the apparatus, and colour thus compared with colour. For this purpose the apparatus is pointed to a brightly illuminated white surface. On looking through the lens of the apparatus a colourless field is seen. Then, by shutting off, one after the other, the single optical systems, we obtain, by direct spectral

subtraction, the complementary colours determining the printing colours.

Mr. Drac thus claims that the system of which he is the inventor gives an absolute solution of the problem of photography in colours by extremely simple technical means, and at the same time introduces exactness into the selection of the

printing colours of the widely used printing processes. From what we have seen of it, there is no doubt of the great ingenuity of the process and of its practical character. It is evidently a step forward in the making of the three-negative colour records, particularly in the direction of reducing the time exposure.

## THE "SOLGRAM" COLOUR PROCESS.

AMONG the communications on colour photography which have reached us since the opening of the exhibition is one from an English reader, enclosing a specimen of the so-called "Solgram" process. We referred to this method some time in commenting upon the ambiguous accounts of it in the American Press, and we are therefore glad to have the opportunity of examining it, so far as a specimen and its author's printed circular permit us to do. The two, however, should be quite sufficient for the purpose. We have added the specimen to the collection in the exhibition.

The process is of American origin, and according to the inventor, W. C. South, of Downingtown, Pa., it "was devised on simple lines in order to make the theory plain and not theory in order to make the Solgram plain." This is kind of him, because the specimen which lies before us requires absolutely nothing to make it plain, "plain" being defined as "wanting in beauty."

The introduction to the descriptive pamphlet of the process makes good reading.

"The intention of this system of colour-photography is to enable the student in Photographic Art to produce photographs in the colours of nature which will resemble paintings in water-colours. As there is no process or means or producing pictures, which for truthfulness to nature can rival a water-colour drawing executed by a master, I have made the aquarelle my standard.

"Matt surface pictures, whether in painting or photography are considered the highest types of art. *It is a rare thing to see works of fine art varnished. To day oil paintings resembles pastels and the time has come when artists have abandoned molasses atmospheres as unsightly if not unhealthy.* The great charm of water-color painting lies in the beauty and truthfulness of its ariel tones, which are further assisted by the granulous surface of the paper upon which they are usually painted.

"There are some people who think a matt surface print not finished. To them I will say that if polish is finish the Solgram Co. sells a lovely varnish which will make a Solgram print shine like a sheet of plate glass.

"I may add that colour photography need not necessarily be lustre photography. You can add lustre however to color photography. If my process of color photography will be appreciated by the large class of truly artistic workers, I will consider myself amply repaid for my trouble in working out what I believed to be a means of a deeper art expression by photography than by any other process at our command.

"The Author,"

"W. C. SOUTH."

The italics are ours.

In his modesty Mr. South claims that the process differs from all other tri-colour processes 'in that the resultant product is a photograph (not a lantern slide, half-tone cut, or physical print) in the colours of nature.' The usual three negatives are required, taken through the usual filters, but these can be dispensed with, and any ordinary negatives used, and the three printings obtained from this, or you can use two negatives. It is all very easy, you can see every step, cold water does the whole of the toning and fixing, and a print is rarely lost because the operator can correct it, "or, what is better still, he may have a picture far more pleasing than he originally expected or intended." We are further told that the photographer with poetic feeling can produce from his two negatives pictures representing any time of day, "from early morn till shades of night."

Apparently a special crimson or red paper is issued; this is printed under the green screen negative, then rubbed with cotton wool and cold water, and thoroughly dried. It is then painted over with "the blue print chemicals, ammonium ferric citrate, and ferricyanide of potassi," exposed and washed in water, dried, and then coated with

a special gum-bichromate film containing a transparent yellow pigment, and this exposed and developed.

After a careful perusal of the pamphlet this is, we think, what the process may be boiled down to. We are only sorry that it is not possible to reprint the whole thing, for there are some delightful touches of quite unconscious humour which are distinctly American. For instance, this passage, read in the light that we have all of us, practically since the beginning of photography, been trying to make photographs in colours *true to nature*, is almost worthy of Mark Twain. "The fact is that the photographer is bound to get a *color picture of some kind*, no matter how carelessly he prints the Solgram, and his picture will never be untrue to some phase of nature."

Again, in dealing with his "bi-negative" process Mr. South is particularly precise, why even Messrs. Kenneth Mees and Sheppard could not tell us more, or be more exact. We quote the following passage to prove the contention: "From the original negative make a proof upon gelatine chloride or any printing-out paper which will give us a reddish proof. The next thing to do is to place a piece of glass in our printing frame; upon this glass lay the proof face up (picture side up); upon this proof place a fresh unexposed dry plate sensitive surface in contact with the proof; then place the back in the frame, turn the frame over, and *light a match, hold it about two or three feet above the frame*, keeping the light in motion all the time, in order that our plate shall be evenly exposed. *When the match has about burned out the exposure can be considered sufficient.* . . . The grain of the paper proof will, of course, show in your negative, but this will be of no consequence.

It is, of course, quite immaterial as to the size or make of the match, or that when it has about burnt out the operator's fingers will be about burnt. The bi-negative process may thus be carried out, or one negative may be made through a green filter, which is used for the red and blue printing, and another through a violet filter, for the yellow print and half-tone cuts are given of such a pair. Obviously "Solgram" is an elastic process, because the two pictures do not coincide; again, we are told that corrections may be made by using "about four or five drops of citric acid (lemon juice)." We may, to save wetting our prints, use a knife or ink-eraser to take out, and water colours, or the special "Solgram" colours, to paint in, colours. And the book winds up with the following sentence: "Indeed, the photographer who can use colors at all and has an aptness for drawing can often to advantage introduce figures in his pictures."

Now to examine the specimen which is to be hung in the exhibition. The background looks like the surface of the sun, showing "rice grain" structure in blue and orange; in the centre of the picture is a lamp, presumably made in bronze; this is a sort of bronze colour with the high-lights white; an opal shade is not such a failure, because there is less colour in it, and the same may be said of the edges of a book which are nearly white. There is an open packet of chewing gum, a pipe of the same colour as the lamp, some books bound in exactly the same shade of leather or cloth, and two boxes of cigars. We do not happen to know this particular brand, "The Boss," but judging from the name it is the sort which is ornamented with plenty of gold medals, which have been awarded it, and these are reproduced as black, though printed, of course, on the box in Dutch gold leaf.

Considering the somewhat effulgent (this is the best term we can find) articles which have appeared in some of the American photographic papers on the process, we are reluctantly compelled to conclude that either the inventor is not such a good operator as author or else that if he is, as he should be, a perfect operator, the speed with which he sends out damn the process as a flat catching dodge.

## NOTES ON OPERATING.

study the individual, his or her expressions and unconscious poses, vary and modify them as your judgment directs, but, if you want good orders, your customers' recommendation, and good business, above all get a characteristic portrait which expresses something of the individuality of the sitter. Let that be your primary object and the work will please even though it be faulty technically and artistically.

\* \* \* \* \*

Most photographers have the experience continually that the sitters who please them most are not the most favoured by the customer. What is the lesson to be learnt? Clearly the photographer's judgment has been at fault, and his ideas require rearranging. But as a class we are very egotistical, and pretty sure to take the opposite view, viz., that the customers require to be educated up to our ideas.

\* \* \* \* \*

Having realised the necessity for that quality, which we may describe as the soul of operating, we face the question how to obtain it? This is easier to a man of naturally pleasing manner and tactful address than to one lacking that valuable asset. But no matter how difficult at first it may be to adapt yourself to each individual sitter, you are sure of some success if you persist and are in earnest. You must break down the formality and reserve that will exist between the sitter and yourself. Until this is done you can have only a moderate success, and to do it you must keep the photographic part of the business entirely in the background. Do not be in a hurry to begin, but engage your sitter in conversation while you are moving a blind something of the kind, the while observing your sitter carefully with a view to seizing favourable characteristics of pose and expression.

\* \* \* \* \*

The ability to seize instantly on what is good comes partly from practice, but partly depends on your knowledge of human

nature and powers of observation, which you can greatly improve by studying people under varying conditions. I plead guilty to having made hundreds of mental exposures during sermons that have interested me less than the people to whom they were addressed, and I admit a good deal of absent-mindedness when attending "At Homes" and other social functions.

\* \* \* \* \*

Your artistic sense will enable you to convert the result of your observations into a pleasing picture of more or less artistic merit, according to your knowledge and taste. If lacking in those qualities you can certainly develop them by cultivation.

\* \* \* \* \*

A few words about posing. A photographer of my acquaintance, who was for years head operator to one of the largest and most fashionable studios in the North of England said he had dropped posing, and let people pose themselves, which was certainly an advance on the stage in his career when he posed them in positions they did not assume under natural conditions. Having a class of sitters who posed well without his help he turned out good pictures, though had he been more progressive he would have returned to the plan of posing them himself, but in a more sympathetic manner, suggestive rather than creative. Once you have a definite idea in your mind and know how you are going to pose and light your subject, make all necessary preparations, then do the actual posing as quickly as possible, engaging your sitter in conversation while an assistant is focussing and making all ready to work from a secret signal. Cultivate this method of control and you will be surprised at the power acquired in time. Impassive sitters have to be worked up until you fairly drag a bright expression out of them. Your sitter will go away pleased, and often exclaim "I always hated being photographed, but I have quite enjoyed it this morning."

AN OLD OPERATOR.

## A MODIFIED GUM BICHROMATE PROCESS.

At the request of the Editors, I am supplementing the report in the paper by Mr. E. H. Griffin before the Wolverhampton Photographic Society, which appeared in last week's B.J., with a few notes from my experience when working out the process some few years ago.

At the outset, I may say that I am not an admirer of the gum process. All must admit, however, that excellent pictures have been produced by a few workers, but they can scarcely be classed as photographs. I, as a technical photographer, prefer to see technically good photography, as well as artistic productions. Both may be combined in a gum print, but that is seldom the case, for many of the results that have been shown at times at exhibitions have been neither of one or the other. Possibly this is why I am not so much in love with the process. Yet, though one may not be personally an admirer of any particular process, there is no reason why one should not publish anything of possible service to others. In the present instance, this modified method of working is capable of yielding, technically, excellent results as well as artistic ones.

### An Indirect Pigment Image.

I may explain that this method is the outcome of some investigations I had to make a few years ago in connection with the action of light on bichromated colloid bodies, and the continuing

action of light, upon which this modification is based, had to be taken into consideration. Mr. Griffin, in his lecture, reported in last week's JOURNAL (see page 68) explained the Mariotype process: In this it will be seen that the action of light set up in one gelatine film is transferred to, and continued in, another which has not been exposed to light at all. In my investigations I found that the same action could be made to continue in another colloid different from that upon which the light had acted—say, if that were gelatine, it would be continued in one of gum—under certain conditions. In my first experiments free bichromate was present, but I found that its presence introduced an element of uncertainty in working, and I rather expected that if this was washed out of the initial print there would not be this continuing action, but I found this was not the case, for when the free bichromate was washed out of the print and a little bichromate added to the gum, the action went on pretty much the same as if it were left in the first print. Finding this to be the case, I next, with the view to seeing how persistent was this action, tried without the addition of the bichromate to the gum, so as to eliminate the uncertainty pertaining to its presence. Here, again, I found, somewhat to my surprise, that it was unnecessary. It was found that prints made on bichromated gelatine could have the bichromate washed out, be dried, and kept for weeks. Then

they could be coated with a pigmented solution of gum slightly acidified, dried, and developed at any convenient time, even after a week or more keeping.

#### Advantages of Indirect "Gum."

Having settled this point, I next turned my attention to other colloids than gelatine, and I found their action was much about the same. Tragacanth, starch paste, and flour paste all answered well. I then conceived the idea that a process could be worked out that would be of some advantage to workers of the gum-bichromate process, and for the following reasons: When the exposure is made on an unpigmented film there is a visible image as a guide to the right exposure of the print, and when the free bichromate is washed out of the paper the prints may be kept till a convenient time for completing the operations. As the pigment coating has not to be printed through it need not be so carefully applied as if it had to be; also, that more pigment can be added to the gum, so that greater vigour can be obtained, thus avoiding the trouble of multiple coatings and printings to secure sufficient depth of colour. Another advantage I recognised was this: In the ordinary method of working the hardening effect of the light progresses from the surface of the pigmented coating downward, as in the carbon process, hence that portion of the image which is in contact with the paper is the softest and most soluble, so that it has to be very tenderly dealt with in the development, or the more delicate tones may be impaired. In this process, however, the conditions are reversed. The hardening action proceeds from the paper upwards, so that the most insoluble position of the image is next the paper, and the more soluble on the surface of the film. This should give greater scope for what is irreverently, by some, termed "faking," or individual treatment of the picture.

#### Formulae.

In his paper Mr. Griffin gives a preference to gelatine for the initial print, but I prefer either starch or flour paste, as they give a more pleasing matt surface, with great vigour.

Between these two materials I found no practical difference in working. Here are the formulæ I used for both. For the flour:

Good household flour, rich in gluten .....	2 ounces.
Water .....	20 ounces.

Mix into a smooth paste; and boil for three minutes. For the starch paste:—

Bermuda arrowroot .....	$\frac{1}{2}$ ounce.
Water .....	15 ounces.

Mix as above, and boil for four minutes.

St. Vincent arrowroot will no doubt answer as well as the Bermuda, and is much cheaper, but I have not tried it. The pastes are best made over night, then in the morning the solid layer on the top is removed, the mass broken up, and then squeezed through coarse muslin. It is then easy of application. For coating the paper I used a three-inch flat hog-hair varnish brush, working it alternately lengthwise and crosswise, so as to obtain an even coating. If the paper is a soft and porous one, two coatings of the paste may be necessary to fill up the pores and keep the image on the surface. If it is a hard, sized paper, a single coating will suffice. Or the paper may have a preliminary coating of gelatine—say, 1 oz. of dry-plate gelatine to 40 oz. of water. The easiest and quickest way to apply this, if it is a smooth paper, is to place two sheets of it back to back and draw them through the solution, and then hang up to dry. In this way two sheets are coated at once, and they dry flat. When dry they can be separated by cutting off about a quarter of an inch round the edges. If the paper be a rough-surface one this plan will not answer. The best plan in that case is to let the gelatine solution cool and jelly, then break it up, as with the paste, and apply with a brush. For sensitising I used a somewhat dilute solution of the bichromate:—

Bichromate of potash .....	$\frac{1}{2}$ ounce.
Water .....	50 ounces.

On this the paper was floated for a couple of minutes. With regard to the pigmenting of the prints I need say nothing, as the method given in his paper by Mr. Griffin is very similar to that I employed.

E. W. FOXLEE.

## LOCAL AND GENERAL REDUCTION OF PRINTS WITH SANZOL.

HAVING occasion recently to reduce the high-lights of a negative I selected "Sanzol," the newly introduced cobaltamine reducer agent, and followed precisely the maker's instructions, with good results. It then occurred to me to try the effect of this reducer on prints. Not that I particularly wanted to reduce a print, but as the solutions were made up I thought I might as well waste them on some prints as down the sink.

The prints were on bromide, gaslight, and P.O.P. papers, and were all printed under an actinometer with a series of opacities ranging from bare glass, reckoned as 1, by geometric progression to 1,024, this last corresponding to an H. and D. density of 3.01, which is quite beyond that obtained in ordinary work. For the purpose of these experiments the development papers were exposed and developed till a distinct and easily seen image was obtained under the densest square, and the lowest squares, corresponding, of course, to the shadows of a negative, were totally ignored, because I wanted to see what the action of "Sanzol" would be on the fine high-light detail, as well as on the shadows of the print.

Precisely the same idea was followed with the P.O.P., only gelatino- and collodio-chloride prints were made, in order to determine whether the vehicle for the sensitive salts played any part in what might happen.

The solution as recommended by the makers was first used, and dealing first with the developed prints I could trace no difference of action between the gaslight and bromide papers, but whilst "Sanzol" will be found useful for reducing excessively heavy shadows, there is distinct action on the high-lights. In both test prints the deposit under the 1,024 square was eaten away. On the other hand, whilst on the original print the three lowest squares were absolutely one uniform black patch, after reduction they could all be differentiated. The duration of the reducing action was five minutes.

#### Reducing P.O.P. Prints.

As regards the P.O.P. prints, I at once met with distinct and strong action on the high-lights. The deposit under squares 1,024 and 512 disappeared before there was adequate reduction in the lower squares. Abandoning, therefore, the makers' instructions, the solution was diluted with an equal quantity of water, and now, whilst the action was more satisfactory, I met with the trouble of blistering.

Nitric acid was therefore abandoned, and citric used in place of it. This introduced the trouble of very strong and distinct staining of the film, but whereas with the nitric acid the high-light detail was eaten out, with citric acid there was

an absence of this defect, and the shadows were considerably lightened. The actual reducing solution used was:—

"Sanzol" .....	1 grain.
Citric acid .....	10 grains.
Water .....	1 ounce.

Experiments with glacial acetic acid were also successful, but I have not had time to carry the experiments to that conclusion which I should do.

Whilst the use of the organic acid reduces the action on the high-light detail, it produces a very strongly coloured deposit on the print, and also entirely alters the tone. Whereas the gelatino-chloride prints were, before treatment with "Sanzol," of a rich purple brown, they afterwards distinctly showed nothing but cold purple or bluish tints. The gelatine prints showed much greater change of colour than the collodion prints, and a greater reduction generally.

#### "Sanzol" as a Local Reducer.

Submitting development prints to the action of "Sanzol" plus organic acids, I found the deposit troublesome, as it prevented anything like an accurate determination of the reduction, and quite casually I wiped a print with a tuft of cotton wool, and found, or thought that there was, more reduction at once. This point was followed up, and, abandoning P.O.P., development papers were tried, and treated with "Sanzol" plus nitric acid and also plus organic acid. After immersion in the reducing solutions till they were thoroughly soaked the prints were laid face up on a sheet of glass, and the lowest square selected for treatment; this was gently rubbed with a tuft of cotton wool saturated with the solution, the other squares being meanwhile also kept saturated with the solution. I then found that I had so reduced the greatest deposit that it now corresponded in intensity or depth of deposit with the fourth square—that is, with the square of opacity 8. It then occurred to me that possibly mechanical attrition plus "Sanzol" would give us another local reducer, and I found that I could reduce any square at will, and could wipe out no less than the three highest squares with practically no friction. The slightest pressure seemed to wipe the image right off the paper.

These experiments were made without photometric measurements of the prints; any change in the print was controlled by mere visual comparison with an untreated print, and whilst therefore very rough and ready they may lead others to try "Sanzol" for local reduction.

As regards the cobaltamine deposit and stain upon the prints, and these are very marked when organic acids are used, the ammonia bath at once removed them. I found, however, that if the ammonia was much stronger than that advised by the makers blisters occurred on all the papers that I used.

#### The Effect on Sulphide Sepia Prints.

Finally, it occurred to me to see what would be the action of this reducing agent on bromide prints which had been submitted to sulphide toning, and I must at once confess that I was surprised at the results obtained, for it is generally accepted that silver sulphide is one of the most stable salts known; yet I obtained a distinct action. I am not prepared to maintain that what I met with was a reducing action, but that there is action is indubitable.

The first experiment was made with prints exposed under my actinometer, and I congratulated myself that my preconceived opinion as to the stability of the silver sulphide image was confirmed. Anxious, however, to make sure more certain, some prints were developed with ferrous oxalate and metol-hydroquinone, and to my astonishment I found a distinct change of colour in the ferrous oxalate developed prints, and

that with the metol-hydroquinone prints I could wipe out the high-lights.

I am not prepared to say that there is reduction of density; there is reduction in intensity of colour—that is, a rich brown becomes a yellower tint—and one can reduce the high-lights when the paper has been developed with metol-hydroquinone. Whether this applies to all development papers and all developers I am not prepared to say. Possibly Mr. Smith, who is, I believe, the discoverer of the action of cobaltamine salts on the silver image, may be able to help us. These notes are merely advanced in the hope that someone else can and will take up the subject; someone with more leisure than I have, for if we could add to our present resources a local reducer which would not only be under control, but allow us to tone sulphide-toned prints, the picture-making powers of the pictorial worker would be enhanced.

E. J. WALL.

#### A FOUNTAIN WINDOW-DISPLAY.

PHOTOGRAPHIC dealers in certain districts might find the installation of a window display, such as we see described in the "Keystone" (America), quite an attraction to the passer-by. Wherefore we reprint the portion of our contemporary's instructions which is necessary for the making of the appliance:—"Have a tinsmith make the centre bowl (marked A in the above illustration) of tin, of any size desired, according to the size of the window. This centre bowl should be shaped like a large cake-tin, hollow in the centre. Cut a hole in the centre of the window-floor and place the tin bowl over it. Put a large rubber band around the centre tin cone. Secure a circular glass shelf, B, having a hole in the centre, and rest it upon the cone.

"Have the tinsmith make a fancy stem, C, enamel it white, punch fine holes in it at the top and bottom and solder it to the water-pipe, which passes through the hole in the centre of the glass shelf and which is attached to the main pipe in the basement. Put a rubber washer on the glass shelf to make it watertight. The water flow is regulated by the water-stop, and the surplus is carried off through the waste pipe.

"Make a skeleton pulley, D, with a piece of coloured glass in each of its openings. Use red, green, yellow and blue glass, and fasten it in position with tacks. Arrange this pulley so that half of it is in the centre of the fountain.

"Place a strong electric light, with a reflector, in the position shown at F, so that it sends its rays upward through the coloured glass and through the centre cone on the water. The effect will be most beautiful. The changing of the colours can be reduced to speed by means of the reducer E. In the lower bowl lay three electric bulbs coloured green, with wires made waterproof, well insulated and enamelled."

## Exhibitions.

### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual exhibition of members' work was opened last week at Eberle Street, and will remain open until February 16. The chief award, the gold medal, for a set of three prints, has been awarded to Joseph Appleby. The two silver medals have been won by Messrs. C. F. Innton and Stuart, the former sending three figure studies in the best of his well-known style. In other classes medals have gone to Messrs. Innton, J. D. Johnston, Colonel Pilkington, W. H. Marquis, H. K. Byrne, A. R. Macleay, and C. A. Hutson, with work well above the average. The president's prize for the best single picture by a member who has never won the society's medal before goes to an exquisite carbon, red in tone, with a delightful effect of sunshine, by A. R. Macleay. There is a good entry of prints in the "Humorous Class," and the medal will go by the popular vote of the members—the voting taking place during the exhibition. In the Scientific Section, Dr. Heatherley exhibits "Studies of Birds," and there are microphotographs of diatoms, by P. T. Aman.

### SOUTH ESSEX CAMERA CLUB.

THE fourth annual exhibition was held from January 25, 26, and 27 in the East Ham Town Hall. In addition to a very creditable exhibition, a series of concerts and other attractions were provided, and every credit must be given to the honorary secretary, Mr. T. Michell, and his committee, in whose hands were the arrangements. The judges, A. Horsley Hinton and H. Snowden Ward, made the following awards in the open classes:

Class A (Landscape and Seascape).—Silver medal (No. 11), "Even-tide," J. E. Latham; bronze medal (No. 19), "Summer Afternoon," F. L. Warner.

Class B (Portraiture).—Silver medal (No. 46), "Beyond," D. J. Scott; bronze medal (No. 43), "Intent he Seemed and Pondering Future Things of Wondrous Weight," Miss M. Woods.

Class C (Architecture and other subjects not included in A and B.).—Silver medal (No. 59), "Flying Gannets," W. Farren; bronze medal (No. 63), "Through a Norman Arch," T. R. Somerford.

Class D (Lantern Slides).—Silver medal, F. G. Tryhorn; bronze medal, F. Judge.

## Patent News.

*Process patents—applications and specifications—are treated in Photo-Mechanical Notes.*

The following applications for patents were made between January 15 and 20:—

HAND-CAMERAS.—No. 1030. Improvements in hand-cameras. Samuel Dunseith McKellen, 19, Cannon Street, Manchester.

PHOTOGRAPHY.—No. 1037. An improved system of photography. Arthur Augustus Brooks, 57, Barton Arcade, Manchester.

TRIPODS.—No. 1298. Improvements in tripod stands for photographic cameras. David Johann Heinrich Simonis, 53, Chancery Lane London.

CAMERAS.—No. 1317. Improvements in folding photographic cameras. Optische Anstalt C. P. Goerz Aktien-Gesellschaft, 31, Bedford Street, Strand, London.

SHUTTERS.—No. 1412. Improvements in photographic shutters. Auguste Romanet and Gaston Guilbert, 115, Cannon Street, London.

PRINTING FRAMES.—No. 1563. Improvements in photographic printing frames. Marwood Short, 37, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

DARK SLIDES.—No. 117, 1905. The invention consists of a dark slide in which the plate is changed in position from the outside of the slide. The invention is to provide a substitute for the turnbuttons, or other fastenings employed in a dark slide to hold

the plate in position, and consists of fasteners operated by a side bolt, which passes through the side of the dark slide. Arthur Lewis Adams, 26, Charing Cross Road, London.

A SMOKE-TRAP FOR FLASH LAMPS.—No. 25,750, 1905. The invention consists of a bag which completely encloses the source of light, is closed on all sides, is collapsible, transparent, or translucent, water-tight and smoke-tight, and is closed during and after the flash. The bag may be made of any material or fabric which is flexible or capable of being folded, transparent or translucent, and has an opening which can be closed smoke-tight and serves on the one hand for introduction of the lamp and on the other hand for cleaning. To make the bag unflammable and impervious to smoke, it is only necessary to wet it. It may, however, be made unflammable in any known manner, or it may be coated with some form of wax, rosin, gelatine, caoutchouc, gutta-percha, or the like. The main feature of the bag is that during the flash it is closed, impervious to smoke and of such a size that it can catch the whole of the smoke evolved. Finally parts of the bag, for instance its back, may be made of opaque or reflecting material. The unavoidable expansion of air accompanying the flash, which would burst the bag, is rendered harmless by collapsing the bag as far as possible when the lamp has been introduced, and when closing it tight, so that it is fully blown out by the pressure produced by the flash. The most advantageous construction is a bag which is broad at its upper part, narrow at its lower part, capable of being opened at the top or at the side, but also of being tightly closed; it is made water-tight in order that the water may be poured in for the purpose of wetting the walls and cleaning them. In the bag is the lamp which is ignited from outside, preferably electrically or by a cap. Inasmuch as this device remains closed during the flash, it catches all the smoke with certainty, and needs only to be washed occasionally in order to be always ready for use. Julius Feider, 70, Romergasse, Vienna, and Ferdinand Hrdliczka-Csiszar, 96, Zieglergasse, Vienna.

PAPER DARK SLIDES.—No. 5,822, 1905. The claim is for a dark slide and envelope for plates or films which is an improvement on that of Patent No. 16,821, 1898. In the present invention the sheath-like shutter or cover is completely removable. Its return is made possible by such a construction of the dark slide, that in addition to the shutter also the film or film-carrier (or an extension attached to the film or film-carrier) and the frame, in which the film or film-carrier is housed and in which also the shutter is guided, extend into and beyond the slit of the camera back or the adapter. Max Staehler, 29, Margaret Street, London, W., for Carl Zeiss, Jena, Germany.

PACKING AND CHANGING FILMS.—No. 9,440, 1905. The specification describes the device whereby the magazine in which films are sold on the system described in Patent No. 9,323, 1905, is used as the receiver for the exposed films from another magazine. Jules Carpentier, 20, Rue Delambre, Paris, France.

SELF-TONING PAPER.—No. 19,850, 1905. The paper is prepared by introducing the gold with a dye-stuff such as methyl violet, fuchsine, or the like into an emulsion containing silver, in which the silver is present partly as cyanide or sulphocyanide. Accordingly to the silver-containing emulsion (collodion, gelatine, albumen, or the like), there is added a dye-stuff of the kind referred to, for instance in the proportion of 5–15 milligrams to 1,000 grammes emulsion, and alkaline cyanide or sulphocyanide for instance in the proportion of 3–6 grammes, as also old chloride or the like in such proportions, for instance 2–3 grammes, that the gold is present in sufficient degree of concentration in the self-toning paper. The toning—i.e., the reaction in the water or salt bath or like bath, proceeds, as above mentioned, with the employment of the improved paper in a surprisingly short time and with absolute security. According to the proportion of salt in the bath the tone can be varied with exactitude from red-brown to the most extreme blue black. There is no risk, and no special attention is required in the toning operation. Experience has proved that the principal effect of the dye-stuff is to prevent the reaction between the silver- and gold-salts while the paper is kept. Such reaction undoubtedly takes place with the self-toning papers hitherto known, and the result is that these

papers, as already pointed out, cannot keep. Moreover, the dye-stuff has a favourable influence on the toning. The circumstance that the toning is effected immediately and with a pre-determined tone is, of course, in the first instance due to the presence of the silver-cyanide or -sulphocyanide, but the dye-stuff ensures that the toning is effected evenly and with a uniformly excellent result. Thus, the object of this invention is to provide a self-toning paper which is not only durable, and gives a genuine durable gold tone on dipping in a salt water or like bath, but has also the special property that the gold tone is independent of the duration of the bath, and is determined only by the concentration or composition of the baths so that with a given property of the bath a definite tone will always be obtained without fail, which is instantly formed and does not alter even if remaining a long time in the bath. Carl Sofus Poulsen, Valby, Copenhagen, Denmark.

**CINEMATOGRAPHS.**—No. 6,436, 1905. The invention consists of a cinematograph camera, also applicable for ordinary photographic purposes with a plate-holder, the camera body being divided into a front chamber and a rear unobstructed film-chamber by a removable partition, which constitutes a holder for the actuating mechanism. The latter is entirely mounted on the front of the partition and without the aid of any contrivances for winding the film with positive motion for the exposure and of special winding-up devices, by means of a cylinder or drums, feeds the film after exposure direct into the rear chamber, where it lays itself in folds wholly unobstructed. Max Hansen, 22, Nachod Strasse, Berlin.

**ADDENDUM.**—By an oversight last week in abstracting the film package patent of J. E. Thornton, the date was wrongly given

as 1905 instead of 1904, and the explanatory diagrams were omitted. The latter are now given, and should be studied in reference to the description on page 70 of the "B.J." of January 26.

## New Books.

THE "Photographischer Almanach" of the firm of Liesegang reaches us in its 26th annual issue, containing a number of technical articles by German writers and an appreciation of A. Horsley Hinton, by E. O. Hoppe. There is a fragmentary review of the practical hints of the year, and the usual notices of new goods on the German market. The price of the "Almanach" is one shilling and the publisher M. Eger, Leipzig.

## CATALOGUES AND TRADE NOTICES.

THE Kodak Company notify us of special displays of Kodak and general photographic goods for the 1906 season which will be held daily until February 28 at 57-61, Clerkenwell Road, 72-74, Buchanan Street, Glasgow, and 96, Bold Street, Liverpool. The display includes the latest models of the Brownies, Folding Brownies, Folding Pocket Kodaks, Cartridge Kodaks, the Screen-focus and Stereo Brownie Kodak, the new Quick-focus Kodak, a full series of Premos, the Premo Film Pack in its latest form, the Kodak Tank Developer, and a full line of general goods.

A new list of telephoto lenses reaches us from Messrs. Steinheil, of 7, Theresienhöhe, Munich. The list, which is fully illustrated, catalogues the new telephoto objectives made specially for hand-cameras, and includes also some tables drawn up to save the usual calculations in this class of photography.

The latest (January) price list of chemicals for photographic and photo-mechanical processes reaches us from Messrs. Harrington Brothers, 4, Oliver's Yard, City Road, E.C.

MESSRS. John J. Griffin and Sons, Limited, are finally vacating the premises formerly having the address Sardinia Street, but now standing on Kingsway. Their new establishment is a handsome block on the opposite side of the road, and, before moving into it, they are offering a number of cameras and other pieces of apparatus at prices which, in many cases, are one-third the usual one. A list of these goods, which can now be inspected, is sent post free.

THE Thornton-Pickard catalogue for 1906, which has reached us from the Company at Altrincham, is artistically a very fine production, and on that account alone is noteworthy as showing the value which a firm like the Thornton-Pickard Co., manufacturing high-class instruments, sets upon appropriately good printing. The chief inducement, however, to seize the offer of the Company to send the list free to readers of the B.J., is of course the very full specification and illustration of the various T.-P. shutters, cameras, and accessories. The company has always spared no pains to lighten the task of the purchaser unable to examine its goods on a counter, and the present catalogue is, if anything, still more explicit and descriptive. It describes, among other new T.-P. introductions, a new half-plate set, the "Imperial Perfecta," a triple extension high-class camera at a popular price.

## New Materials.

**Silvo Postcards and Paper.** Made by the Rotary Photographic Company, Limited, 12, New Union Street, Moorfields, London, E.C.

To their long series of rotary papers the Rotary Photographic Company have now added another—viz., one which enables the worker who is able to use either a bromide or gaslight paper to produce prints of silver-like lustre without any departure from his ordinary methods. Printing papers, incorporating a flexible metallic support, have appeared upon the market from time to time, but cannot be said to have enjoyed very long spells of popularity. It is to be hoped that the Rotary Company, with its great facilities of distributing any new product, will be able to create a demand for a deservedly notable departure from the usual kind of photograph. We have found the "Rotox-Silvo" papers submitted to us capable of yielding excellent results when put through the customary routine of exposure and development, and we can well believe that professionals might create some amount of interest among their customers by means of it. The price of the postcards are 1s. per packet, and the papers are obtainable in all the cut sizes at prices based on 8d. per dozen quarter-plates.

**EDWARDS'S Lantern Plates.**—A special interest attaches to the receipt at the "British Journal" Office of samples of lantern plates from Messrs. B. J. Edwards and Co., of Castlebar Works, Ealing, inasmuch as the occasion marks the issue of manufactures under the direction once more of Mr. B. J. Edwards, the founder of the firm and the first manufacturer of isochromatic plates in England. Though the plates are thus old established, it is admissible for us to depart from our usual custom of reviewing only new introductions on the market, since users of Edwards's products who may have had occasion for complaint may be glad to learn that the technical

management of the business is now in the hands of its originator, by whom no effort will be spared to render the current output worthy of its traditions. To leave generalisations, we find the "special transparency" plates give us slides of black or warm tones of great richness and of fine grain. They are obtainable in the usual way from the dealers.

**COLD AND WARM TONES ON MATT PAPER.**—The double method of toning first with gold and afterwards in a platinum bath is, of course, widely known and practised by users of print-out papers, but it does not appear to be generally recognised that the two metals may be employed together in one bath—that an acid one. Acid gold baths have been advocated, it is true, so that the employment of gold in a state other than that of faint alkalinity, which is usually adopted, is not without precedent. The use of such a combined gold platinum bath was brought to our notice recently by a demonstration of the treatment of "Mattos" paper, a new print-out plain paper sensitised on a hand-made Whatman paper. The bath employed and prescribed in the "Mattos" instructions is strong in platinum, and its content of gold chloride is less than one-thirtieth that of potassium chloroplatinate. In this bath the prints are toned without any preliminary washing and quickly pass to a stage which gives an extremely fine black tone after fixing. The bath can be used repeatedly until exhausted, but an old bath favours the production of fine brown and sepia tones, and should, in fact, be kept for that purpose. We were also shown the tones obtainable on "Mattos" by simple fixation with and without a preliminary bath of ammonia. The results are rich warm sepias and purplish browns, admirably suited to the close yet broad texture of the paper. It is thus evident that "Mattos" paper has certain strong claims upon photographers—and particularly professional photographers—by whom further particulars can be obtained from 6, Holborn Viaduct, London, E.C. On the occasion of the demonstration we were shown by Messrs. Thornton some specimen prints on wood sensitised as "Mattos," and were given to understand that it would be possible to place a flexible sensitised wood of very velvety surface upon the market at a moderate price.

## New Apparatus, &c.

**Christy's Damper.** Sold by Thomas Christy and Co., 4, 10, and 12, Old Swan Lane, Upper Thames Street, London, E.C.

For many purposes, in the photographer's or photographic dealer's despatch room, the little piece of apparatus shown in the drawing should be found most useful. It consists of a roller covered with coarse flannel and mounted below a reservoir containing water. The

latter is fed on to the flannel-covered roller by capillary attraction, through the medium of cotton packing placed in the aperture of the reservoir. The water is thus distributed evenly and gradually to the flannel, which is thus preserved in a convenient state of dampness. For moistening labels, wrappers, stamps, etc., the apparatus is obviously a convenience. Such we have found it during our short possession of it, and we have no doubt that our experience will be that of others. It is even conceivable that it may find a place in the photographic workroom in circumstances where it is desired to apply an even coat of solution to any surface. The reservoir is of brass, and, therefore, should not be used as the receptacle

of many sensitising solutions unless first silvered, but in its present state the accessory is such a speedy and desirable substitute for insensitising methods of applying moisture that it should make a place for itself in offices and workrooms. Its price is 3s. 6d.

## News and Notes.

**The Bolton Amateur Photographic Society** holds an Open Exhibition on April 18, 19, and 21, in the Victoria Hall, Knowsley Street, Bolton. Particulars and entry forms may be obtained from the hon. secretary, Mr. T. W. Cross, 27, Latham Street, Bolton.

An exhibition is to take place at Easter week in connection with the Redcar Photographic Society.

A course of elementary practical lessons in photography commences at the Cripplegate Institute, Golden Lane, E.C., this evening (Friday), at 7.15. The class is open to ladies and gentlemen, and will be in the hands of Mr. C. W. Coe.

**PYRO FOR STAND DEVELOPMENT.**—In reference to our promise last week for a "stand" developer, M. A. Levy writes to us from Amieres, France, stating that he regularly uses pyro for the purpose, and finds that if well diluted it does not give rise to stain.

**FINGER-NAIL PORTRAITURE.**—The latest Society fad, according to the daily Press, is the wearing of photographs upon the finger-nails. A few weeks ago it was photographs on waistcoat buttons, but that has been displaced by the finger-nail craze, so we are solemnly assured by one halfpenny journal. We have not yet met with any ladies adopting the alleged correct style of carrying their husbands' fiancées portraits on the finger, but perhaps our experience has been uncommon. If the wish is father to the thought, the rumour might have been started by a photographer, for we read that the price of a finger-nail portrait is half a guinea, and at the end of three weeks the growth of the nail has necessitated its renewal. Quite an ideal kind of business.

**CINEMATOGRAPHY IN COLOURS.**—As announced in THE BRITISH JOURNAL OF PHOTOGRAPHY last week, a demonstration of cinematography in colours was given at the Royal Institution, Albemarle Street, W., last Friday, by Captain W. N. Lascelles-Davidson and Mr. W. Friese-Greene. The projections, which were on a small scale, created a good deal of interest among the scientific audience, and were pronounced to be a great stride forward in colour photography. Some speculation was indulged in on the preparation of a colour-sensitive film of quality to obtain the balance of colour-sensitiveness for the two filters through which the exposure is made. It was explained that the results were obtained by the combination of a very sensitive, specially orthochromatised, adjusted light filters, a quick lens, and a good light. The spectators expressed themselves surprised at the brilliance and accuracy of the colours. One gentleman was heard to predict a great future for cinematography in colours, as applied to scientific investigations, such as spectrum analysis and solar physics. The apparatus was examined by a number of those present.

**The Invention of Bromide Papers.**—Mr. John Nicol, the veteran editor of "The American Amateur Photography," writing in a recent issue on the article by Mr. Burgess in THE BRITISH JOURNAL OF PHOTOGRAPHY, says:—"Mr. Burgess claims the invention of bromide paper, while he was superintendent of Morgan and Kidd's factory during the first year of its existence. Just when that was I do not remember, but I do remember that a considerable time before that Mr. Swan [now Sir Joseph Swan—Eds. B.J.P.] appeared before the members of the Edinburgh Photographic Society and showed bromide paper, as a reference to its minute book will show. Of course, I know that not always the man that invents, but he that brings into practical use deserves the credit and also gets the dollars, but the introduction of bromide was a big thing, and it is but right that the credit should go to the right man. Mr. Burgess may have made a better gelatine emulsion before Dr. Maddox, but he kept his thumb on the emulsion and sold it, while Dr. Maddox published his, and there lies all the difference."

Last week a fire broke out in the house of Mr. J. Trotter, photographer, Comrie Street, Crieff. A chimney had gone on fire, and owing to its construction some joists were ignited.

**ROYAL PHOTOGRAPHIC SOCIETY.**—The paper by Mr. T. Thorne

Baker, on "The Applications of Spectro-Photography to Chemistry," is postponed from February 27 to March 27. On the former date a lengthy paper will be read by Messrs. C. E. Kenneth Mees and S. E. Sheppard, on "The Estimation of the Colour Sensitiveness of Plates," consisting of an historical introduction and an examination of the methods of adjustment of the light used, Eder's two-colour method, three-colour testing, bathed plates, spectrum tests, possibilities of spectro-sensitometry, and some results with pinacyanol.

## Commercial & Legal Intelligence.

**BANKRUPTCY of a Builder-Photographer.**—George Edmund Wren, builder and photographer, 17, Copenhagen Road, Gillingham, appeared for his public examination at the last sitting of the Rochester Bankruptcy Court, before the Registrar. Debtor attributed his failure to depreciation in the value of property and slackness in trade. In reply to questions put by the Official Receiver, debtor said he started in business in 1877, with a capital of £40, and took contracts for carpenters' work up to 1885, when he removed to Copenhagen Road. He learnt photographing while suffering from the effects of an accident. Between the end of November, 1904, and the end of January, 1905, he made a profit of £105. He had twice previously made arrangements with his creditors. In 1887 he paid a dividend of 15s. or 16s. in the £1, and six years later his creditors accepted 10s. in the £1. The business was arranged mostly in the office of Mr. Bessent, who had the receipts. The examination by the Official Receiver showed that the debtor had been involved in very considerable building speculations, and that he had allowed his collections of accounts to be very lax. The debtor was allowed to pass.

**INSTRUCTION in the Bioscope.**—At Shoreditch County Court on Thursday, Mr. Thomas Charles Field, bioscope operator at the Palace Theatre of Varieties at Bow, sued Mr. Maries, of Dalston, to recover £2 18s., balance due for lessons on the bioscope. The plaintiff said the defendant asked him to teach him the use of the bioscope to enable him to better his position in life, and eventually was able to take a position at Morecambe. A verdict was given for the amount claimed, with costs.

**FRUITS of the Coupon Business.**—On Monday last the Stockport magistrates investigated charges of obtaining money by false pretences with intent to defraud brought against a Manchester woman named Elizabeth Shannon. They decided that the evidence was not sufficiently clear, and giving the accused the benefit of the doubt, discharged her. It was alleged against the woman that she went round the shopkeepers representing that she was the agent of Mr. J. C. Bradshaw, photographer, of Victoria Street, Manchester, and offering what she said were special terms for one week only for shopkeepers. Evidence was given by three witnesses that they paid her money for photographs. The photographs were to be taken at a new studio which the prisoner said had been opened on Lancashire Hill, Heaton Norris, by Mr. Bradshaw, and coupons entitling the purchasers to the photographs were given. One of the witnesses, Mrs. Ethel Bent, said that she arranged to have her photograph taken in her wedding dress, but when she went to Lancashire Hill she found no studio there. Mr. Dobson, who prosecuted, said that there were a large number of similar cases in Stockport and Levenshulme. The prices paid for the photographs varied according to size—in one case 2s. 6d. was paid, in another 1s. 6d., and in a third 1s. The money was not forwarded to Mr. Bradshaw. Mrs. Bradshaw, the wife of Mr. J. C. Bradshaw, said that shortly before Christmas the accused applied for a position as agent. She was told that there were no vacancies, but she was allowed to have a coupon book in order to introduce any business she could. She had no authority to offer special terms to shopkeepers or to say a studio had been opened on Lancashire Hill by Mr. Bradshaw. Mr. Bradshaw had never any intention of opening a studio in Stockport. The police evidence was to the effect that the prisoner when arrested gave two false names and a wrong address. In reply to the charge she said she had no intention of defrauding. Mr. Dobson explained that the coupon system was adopted some time ago and was used by many photographers as a way of getting business. The magistrates were absent from the bench for some time considering their decision.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
2	Aberdeen Amat. Photo. Assn.	Federation Portfolio.
2	Colne Camera Club	"Pictorial Composition." Mr. J. Emmott (Nelson).
2	Sutton Photographic Club	Photography 1905 Prize Slides.
2	Watford Photographic Society	Lectures by Members.
5	Scarborough and Dis. Ph. Soc.	Y.P.U. Lantern Slides.
5	Widnes Photographic Society	"Insect Hairs Curious and Beautiful," Mr. F. W. Saxby.
5	Motherwell Y.M.I. Cam. Club	"Wet Collodion Process." Mr. Henslowood.
5	Leek and District Photo. Soc.	Lantern Night. Lecturette. Mr. W. H. Nicksdale.
5	Bowes Park and Dis. Ph. Soc.	Outing. Lantern Slide Competition.
5	Heaton & Dis. Camera Club	"Manipulation of Plates and Improvement of Faulty Negatives." Demonstrated. Mr. Gardner.
5	Dewsbury Photo. Society	"Ceramic Photography by the Powder Process." Demonstrated. Mr. J. Skelbeck.
5	Oxford Camera Club	Annual General Meeting.
5	Catford & Forest Hill Ph. Soc.	"Pictorial Possibilities." Mr. J. W. Budge.
5	Southampton Camera Club	Lantern Slide Competition. Landscape.
5	Halifax Camera Club	"Some Ruined Castles, their History, Antiquities, and Anecdotes." Mr. J. Marston.
5	Wandsworth Camera Club	Affiliation Lecture on "Flower Photography."
6	Royal Photographic Soc.	"Notes on Cathedral Photography." Mr. H. W. Bennett.
6	Manchester Amat. Photo. Soc.	"Making Transparencies for Enlarged Negatives." Mr. O. J. Harrison.
6	Stafford Photographic Society	"Systematic Exposure and Development." Mr. H. Cliff.
6	Sunderland Camera Club	"Intensification and Reduction of Negatives." Mr. Bert Jackson.
6	Gloucestershire Photo. Society	Lecture. Mr. R. W. Dugdale.
6	Newcastle-on-Tyne Photo. Assn.	"Architectural Photography." Mr. A. E. Cowling.
6	Brentford Photo. Society	"Marine Photography." Mr. F. J. Mortimer, F.R.P.S.
6	Orley & Dis. Cam. & Art Soc.	Y.P.U. Set of Lantern Slides.
6	Birmingham Photo. Society	"Taste." Mr. R. Catterton-Smith.
6	Sheffield Photographic Society	"The Elements of Architectural Photography." Mr. J. R. Wigfull, A.R.I.B.A.
6	Nelson Photo. Society	Amateur Photography Prize Lantern Slides, 1905.
6	St. Helens Camera Club	"Old Widnes." Mr. C. Poole.
6	Darlington Camera Club	"Zigzag and Carbon." Demonstrated. Thos. Illingworth & Co.
6	Bristol Photographic Club	"The Camera as a Diary." Mr. G. Rasmussen.
6	Jersey Photographic Society	Affiliation Competition Prints, 1904.
7	Coventry Photo. Club	Judging Autumn Prints.
7	North Middlesex Photo. Soc.	Lantern Slide Competition.
7	G.E.R. Mechanics' Institution	"Velox and Its New Applications." Demonstrated. Mr. A. W. Green.
7	Leeds Camera Club	"Telephotography." Illustrated. Mr. William A. Furse.
7	Edmonton and Dis. Photo. Soc.	Lantern Lecture. Mr. E. T. Coombes.
7	Cricklewood Photo. Society	Competition Portraiture.
7	Everton Camera Club	"Dry Mounting." Mr. Herbert Holmes.
7	Edinburgh Photo. Society	"Wireless Telegraphy." Mr. G. J. Drysdale.
7	Redcar and Coatham Ph. Soc.	"Some Scottish Abbeys by an Englishman." Illustrated. Mr. E. Darwin Wilmot.
7	Photographic Club	Yorkshire Photographic Union Portfolio. Members.
7	Hampstead Scientific Society	"Novelties in Printing Papers." Mr. T. W. Derrington.
8	Rugby Photographic Society	"Copying." Demonstrated. Mr. O. C. Quekett.
8	Fulsey and District Photo. Soc.	Members' Night.
8	Liverpool Amateur Ph. Assn.	Members' Competition.
8	Wallasey Amat. Photo. Soc.	Bromide Prints.
8	Hastings and St. Leonards P.S.	"Composition of Line in the Figure." Mr. Fred. Burridge, R.E.
8	Hull Photographic Society	Focus Slides.
8	Southport Photographic Soc.	Ten Minutes' Lecturettes. Members.
8	Rodley, Farsley, & Calverley Dis.	"More French Architecture and a Camera." Mr. J. V. Saunders, M.A.
8	Bolt Court Sch. of Photo. Eng.	Conversation in conjunction with the Southport Society of Natural Science.
8	Richmond Camera Club	"Gum-Bichromate Printing." Mr. J. R. Coulson.
8	London and Prov. Photo. Assn.	"The Present Position of Wood Engraving." Mr. Arthur Dix.
8	Harrogate Camera Club	"A Cruise in Norwegian Waters." Mr. C. H. Davis. "The English Lakes." Mr. J. D. Gibson.
		"The Latest Image." Mr. A. J. Bull. Members' Night.

**LIVERPOOL PHOTOGRAPHIC ASSOCIATION.**—The annual meeting was held last week, Dr. C. Thurstan Holland, the retiring president, in the chair.—After the passing of the annual report and the balance sheet—both very satisfactory documents—the officers for the ensuing year were elected. Mr. Joseph Marples is the new president, Mr. Appleby the senior vice-president, and Mr. F. Gregory Jones the junior. Messrs. Inston, Lockier, and W. A. Taylor were re-elected respectively secretary, treasurer, and librarian; and Messrs. C. Thurstan Holland, E. R. Dibdin, J. Parkinson, F. Anyon, H. E. Cubley, and Harry Holt to the vacancies on the council.

**NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.**—On January 24 Mr. W. Thomas lectured on "Photography with a Hand Camera." He fully explained his own method of working by means of a reflex hand camera of superb make. The adjustments in connection with such a camera, Mr. Thomas pointed out, must be accurate, more particularly in the agreement between the image on the reflector and on the screen. For the most rapid work and work on dull days lenses of large focal aperture must be employed. Examples, by means of slides, were thrown on the screen, of subjects exposed at  $f/4$  and  $f/2$ . With apertures of this character depth of focus is a factor of serious consideration, hence Mr. Thomas's advocacy of a camera of the reflector type, where the image can be seen up to the moment of exposure. With lenses of the above character, rapid orthochromatic plates and suitable screens, the hand camera worker, Mr. Thomas said, was equipped for all classes of subjects, excepting certain kinds of interiors. The lecture was full of suggestions to those who sought by photography means to produce pictorial subjects. The emphasis was perhaps strongest on the idea of taking subjects which would serve as reminders for future guidance, and to utilise them as studies for the development of the idea which they originally conveyed.

**BOWES PARK PHOTOGRAPHIC SOCIETY.**—Demonstrating lantern slide making before the above society, on the 22nd inst., Mr. J. P. Bayne said he preferred a thin negative. When making warm tone slides he over-exposed, over-developed, and reduced in ferricyanide. To clear he advised a weak ferricyanide solution.

**CROYDON CAMERA CLUB.**—The annual meeting was held on the 24th ult. From the report and balance sheet submitted by the secretary, Mr. H. M. Bennett, the past year shows nothing but continued prosperity, together with a large accession of new members. The average attendance has been high, and the fixture list well up to standard. No change of officers takes place, but Messrs. Alexander, Dodsworth, and Stokes succeeded Messrs. Jenkins, Rogers, and Wood, who retire from the council. It was also satisfactory to learn from Mr. Rogers that the recent exhibition had only resulted in a trifling deficit, it standing out in this respect in marked contrast to its predecessor. The president, Mr. W. H. Smith, congratulated all upon the position of affairs, a happy state of things, he very truly said, which was mainly due to the energy and ability of the best hon. secretary it had ever been the club's lot to secure.

**THE Redhill Camera Club** has published its report for 1905, from which we see that its last session has been one of considerable prosperity and progress.

**HULL PHOTOGRAPHIC SOCIETY.**—At the meeting last week, Mr. W. H. Willatt recommended the taking of a portable dark room on one's holidays, so that wet days could be spent in developing plates. His own apparatus was a double-hinged board with frame at each end, fixed up like a book-rack, and black cloth cover, with arm holes and elastic and two glasses and pads to fix in front of eyes, held there by elastic, and the head outside. A ruby glass window in it, with blind inside to adjust, according to strength of light.

**ABERDEEN PHOTO ART CLUB.**—Last week a lecture, entitled, "In the Highways and By-ways," was delivered by Mr. A. Mackilligan ("Luke Round"), a well-known and popular North of Scotland journalist.

**THE SUTTON PHOTOGRAPHIC CLUB.**—The first of the series of photographic instruction evenings was held on Friday at Mr. Bradshaw's studio, which he kindly placed at the club's disposal at short notice, consequent upon the Sutton Society's rooms not being available. There was a good attendance of amateurs to hear the chairman of the club, Mr. Hector Maclean, upon "The Choice and Use of Photographic Apparatus."

## Correspondence.

- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* We do not undertake responsibility for the opinions expressed by our correspondents.

### PLATES v. FILMS.

To the Editors.

Gentlemen,—In reply to "Wet-Plate's" query in your last issue, I would strongly recommend him not to use films if absolute sharpness is required. It is my experience, covering some twelve years' use of films, that with any size over  $5 \times 4$  it is quite impossible to get a flat surface on your film, it either "sags" or, if stretched tightly, it "creases." If you use the thick-cut films, they invariably "bulge." Another disadvantage is that with thin negatives, the grain of the celluloid prints out. Thin glass is undoubtedly best, as far as quality, cost, and ease of manipulation are concerned.—Yours faithfully,  
January 26, 1906.

STELLA.

To the Editors.

Gentlemen,—In reply to "Wet-Plate," may I say that for my work, as an amateur, I have used cut celluloid films up to whole-plate size, almost exclusively, ever since they first came out. Negatives equal to those on glass are obtainable; they print equally quickly. For portability about 1-10 the weight, and, of course, unbreakable; cost, unfortunately, considerably more. With films over  $\frac{1}{2}$  plate they will not keep quite flat, and it is better, if possible, to work at about  $f/16$  or under, although I have snap-shots taken at  $f/11$  and  $f/8$  that are quite satisfactory on whole-plate size. I have used films two to three years old, and found them quite good, and in places as far apart as Egypt and Norway. If many prints are wanted they can be varnished with water varnish; spirit will not do.—Yours faithfully,  
H. G. M. CONYBEARE.

Delmore, Ingatestone.

### THE INVENTOR OF THE ENAMEL PROCESS.

To the Editors.

Gentlemen,—In regard to the letter of Mr. Horgan in your issue of January 19, I think there is no doubt that Charles E. Purton is the inventor of the enamel process. Mr. F. E. Ives, who was a fellow-worker with Purton, has acknowledged this; and Mr. C. E. Chetham, now residing in St. Louis, who was also working in the same establishment, has also borne testimony to the same fact. I met Mr. Chetham in Buffalo last year, and he gave some reminiscences of their early days of process work. He related how Purton used to work in a separate room, which he kept carefully locked, and no one was ever allowed to find out the details of his process. Mr. Max Levy, another of the "old timers" of photo-engraving in Philadelphia, confirmed Mr. Chetham's reminiscences. Mr. McIntyre, of the Electro Tint Engraving Company, Philadelphia, is another who could tell us something about Purton, who is now dead. I think it is only about a year ago that I saw notices in the papers of his death. Purton undoubtedly got his idea from the Garnier process, which was described by Major-General Waterhouse in the "Photographic News" for November 4, 1881. (I was wrong in ascribing the source to an old "British Journal Almanac," although I have often heard it stated so.) I find I have a copy of this article, and, as the paragraph bearing on this subject is a short one, I think you will find the space to quote the same. It is as follows:—

"PHOTO-ENGRAVING OF LINE WORK.—A plate of copper is prepared by covering it, either by flowing or with a roller, with a very thin coating of a solution of:—

Sugar .....	2 grammes.
Water .....	14 grammes.
Bichromate of ammonia .....	1 gramme.

This coating is equalised and quickly dried by means of an arrangement which keeps it in rotation over a warm plate. As soon as the plate is dry, a positive cliché of the drawing to be reproduced is laid upon it, and the whole exposed to the sun for a minute, or to the

electric light for three minutes. The reaction produced is the same as with citrate of iron, but much quicker; the exposed parts are no longer hygroscopic, but in the parts protected by the lines of the drawing the sensitive coating has retained its stickiness, and will hold any powder that may be passed over it, thus producing a very clear image of the drawing. The coating being excessively thin, the little moisture it holds and the powder applied suffice to break its continuity, especially if the powder be slightly alkaline. If the rest of the surface were equally resisting the plate might be bitten at once; but light alone is not enough to produce complete impermeability; the action of heat must be combined with it. The plate is therefore placed on a grating with wide openings, a large flame is applied underneath, and it is heated till the borders where the copper is bare show iridescent colours. The sugary coating thus becomes very hard in the exposed parts, but under the powder it is broken, porous, and permeable to acids. The surface is then covered with the biting of fluid, which is a solution of perchloride of iron at 45 degrees Beaume, and after a few minutes contact the plate is engraved. It only remains to clear off the bichromated sugary coating which forms the reserve, and which, being hardened by heat, resists ordinary washing. It is removed perfectly by rubbing the surface with a hard brush and warm potash lye; the plate is then ready for printing. Sometimes it is necessary to give several successive bitings, or to use a resinous grain; in such cases various methods of the engraver's art are employed."

It will be seen that the process described applies to intaglio etching, but in another part of the article it is shown how it can be applied to relief blocks in the same way, only, of course, using a negative instead of a positive. The inventor, however, suggests powdered bitumen for dusting on the image. It is not stated in the article what powder should be used in the process we have quoted, but Mr. Ives has stated that Purton used a "tin salt." This process has lately come up again as a new thing, under the title of the "dry enamel" process, in which it is understood that the powder is anhydrous carbonate of soda.

With regard to the introduction of the enamel process into England I believe the first to bring it over was an American, named Ryan, who also introduced square stops, and square stops with extended corners. About the same time (1893) the process was sent over from America by a dealer named Sellers to Penrose and Co., and I had the somewhat onerous duty of demonstrating it to the trade. Fish glue was the principal substance used for making the enamel solution. A number of the biggest users of the enamel process to-day first acquired the method in this way. At first it was despised and rejected of men, but as negatives improved and copper became more and more used it soon made headway.

As to the claims of Mr. Hyslop, I have heard it related that he landed in America as a photographer, and found it difficult to get employment, but seeing an advertisement in "Wilson's Photographic Magazine" for a photo-engraver, he bought a copy of Wilkinson's "Photo-Engraving," and steadily "crammed" himself with the subject, then, boldly presenting himself for employment in that line, he was engaged, and proved a very useful man to his employer. I have been unable to find the date of Hyslop's article in the "Artist Printer," but I see Mr. Horgan puts it as the beginning of 1892, which I do not think is correct. I think it was in 1893. "Wilson's Magazine" discovered and quoted the article in a condensed form. The "Practical Photographer" (then edited by Mr. Snowden Ward) reprinted it from "Wilson's" in its number for April, 1893, and the "Photogram" reproduced it in its first number, January, 1894. In the original article Mr. Hyslop states that he bought an enamel formula for fifty dollars, which contained gum arabic as the base, and finding himself unable to work he began to experiment with glues, finally hitting on fish glue. Sellers was the dealer who was selling the enamel process for fifty dollars, and he seems to have adopted fish glue as soon as it was suggested. The late M. Wolfe, the screen maker, of Dayton, Ohio, was also selling a gum enamel formula, but never, so far as I am aware, changed it for fish glue. The sales of fish glue for photo-engraving purposes are very large, and if the makers had paid Hyslop, say one penny on every pint sold, he would have been a very wealthy man by this time.

I think this is about the whole history of the enamel process, but

possibly some of our American friends can fill in more details.—Yours very truly,  
109, Farringdon Road, London, E.C.  
January 25, 1906.

WM. GAMBLE.

### THE LATENT IMAGE.

To the Editors.

Gentlemen,—It appears to me that the paragraph in which you invite criticism dealing with the latent image, in last week's issue, may be divided for my purposes into three propositions:—

(1) That the shape of the curve of a plate is affected by the failure of the reciprocity law.

(2) That the proof of the shape of the curve is rendered invalid by Mr. Sterry's work on primary and secondary development.

(3) That the bending of the over-exposed portion of the curve is, or may in extreme cases be, conditioned by reversal.

Unfortunately, the answers to propositions 1 and 2 arise from investigations which I have completed, but not yet been able to publish, and I must, therefore, ask that they be taken on trust without experimental proof for a little while.

(1) Since we assume equal intensity and differing exposure time in the case of a plate-curve, the failure of the reciprocity law can only affect the shape if the extent of the failure varies with different total exposures for the same intensity. I have measured this with a range between the two exposures of 500 to 1, and found that the reciprocity failure is independent of the exposure.

If we use an intensity-curve in which equal exposure times are given and the intensity is varied (as in ordinary photography), then the reciprocity failure will slightly (usually very slightly) affect the shape of the curve.

(2) Inasmuch as Mr. Sterry's theory of primary and secondary development was directly opposed to the theory of development adopted by Mr. Sheppard and myself (Chemical Dynamia of Development, Proc. Roy. Soc., 74, reprinted in PHOT. JOURN., August, 1905), I at once commenced an investigation of the action of chromic acid upon the latent image, as the result of which I concluded that Mr. Sterry's theory was unnecessary, the results obtained being explicable on much simpler grounds. I believe that Mr. Sterry, who has kindly read this paper, will agree to my results. There appears to me to be very little evidence for supplementary intensification independent of the exposure effect.

(3) Probably if we were to increase the thickness of a plate film enough reversal would begin to condition the bending of the curve, but I do not think that in any ordinary case reversal enters into the question. Mr. Sterry, I think, differs from me on this, but experimental evidence on both sides is vague. Hurter and Driffield's equation failed to represent the effect of reversal for the very reason that reversal is a phenomenon associated with the nature of the latent image, while the shape of the plate curve, which they dealt with, is not.

On the subject of the nature of the latent image itself, Mr. Sheppard and I have been driven by experimental evidence to abandon the physical theories, and to come to a chemical theory almost identical with the modern form of the sub-bromide theory. We hope to publish a paper on the subject shortly.—Yours sincerely,

C. E. KENNETH MEES.

Rylands, Caterham, Surrey, January 26, 1906.

### COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have read with much interest your criticism on the exhibits at your office. I consider your criticisms very fair, and in reference to my own exhibits I am quite aware of the truth of much that you say, but I would like to be allowed to give a few words of explanation. In the first place, all the exhibits must be looked upon quite in the light of experiments. During the past two years we have been groping about looking for the most convenient method of reproducing our colour value negatives as positive prints in colour. Many of the described methods sound very pretty in writing, but when put into practice show considerable difficulties, therefore we have tried first one, then the other to get at the most convenient method. As a practical worker, I am of opinion that the results must be on one surface. The cementing together of films will never give satisfactory results as the reflection from the last surface always

give a preponderance of colour which spoils the general result, when the subject is viewed as a transparency this does not have the same effect, and the result is satisfactory. The imbibition system of one sort or the other appears the most practical and easy method to follow. It must be borne in mind that the exhibition was got together at very short notice, and workers had no opportunity of preparing results, specially for the exhibition, but were compelled to show such results as they happened to have by them at the moment, and I do not think it quite fair to lay stress on minor defects, such as errors of superposition, which can always be corrected in careful work. You lay stress upon error of superposition in certain specimens. These specimens are portraits, and a word of explanation will show how this happens. When a sitter is posing for a three-colour subject there is always a tendency for a slight movement of the sitter to take place at the moment of changing the plates—in producing the finished result to obtain superposition of the figure, especially the face. It is necessary, perhaps, to throw some of the surrounding objects out of superposition. In future, as we shall now take all these negatives at one exposure, this will not occur, and in any case the results are intended to be examined in a broad general way without minute investigation. A painting is not exposed to criticism as to brush marks or peculiarities of pigment. Then again, the tone values are a matter for individual judgment. Some artists prefer to render the colours heavy, others light, but so long as the proportion is the same and the relation correct, the amount of colour may vary. Do we not see variations in the tone value of the same piece of Hampstead Heath, whether painted by Constable, Turner, David Cox, or De Wint. I prefer a heavy effect, similar to Constable, but any other three-colour worker, by simply not putting so much colour into each successive printing, can obtain a lighter and more dainty result. With regard to the curiously coloured stool and flower-pot. These were painted to act as a colour chart, and will undoubtedly vary in different cases according to the different light in which the photographs were taken. It must not be supposed that the same subject will show exactly the same colour by every sort of light. The flower-pot, I may say, is a Wedgwood vase, and to those who bear in mind the colouring of a Wedgwood vase, will appear very faithfully rendered. Another point is that in all three-colour rendering, reflections in colour become much more apparent to the eye than in nature. In nature, the colour reflections are there, but the ordinary eye does not perceive them. Possibly the Editor's black kitten may have had a red reflection on it, for I have noticed a certain amount of colour reflected from a negro's face. So far as I can see there is nothing in nature which is absolutely black in strong sunlight. Surface reflection, which is not noticed by the eye, will show a very marked effect upon the photographic plate. Therefore, I contend that it is not fair of any critic to judge results by what he thinks they ought to be. The photograph is probably more correct than the critic's impression, and it is for three-colour workers to select subjects which will be as much as possible in accordance with popular preconception. In course of time Whistlerian effects may be tolerated, but at present they would only be looked upon as monstrosities. It is sufficient to show that practical and workable means exist by which objects can be reproduced in colour by means of photography. Let this be generally known, and the highly-finished accurately superimposed perfect results will come in time.—Believe me, dear sir, yours faithfully,

EDW. F. GRÜN.

The Hall, Southwick, Brighton. January 25, 1906.

To the Editors.

Gentlemen,—In the account by Mr. Wall in your current issue of your interesting exhibit of examples of colour photography, I note that no mention is made of the method to which I called attention last year in "Focus," and which a few weeks ago you noticed in your pages as an abstract of a lecture given by me to the Worcester Camera Club. The method is, of course, not original, but has been strangely overlooked. I venture, therefore, to send you half a dozen examples of the method, which I hope may find a place in your show. In every case the process is the same—viz., starting with a ferro-prussiate print; subsequent red and yellow prints are made in gum. The screens through which the negatives were taken were prepared by myself, and are gelatine films stained with diamond dyes.—Yours very truly,

JOHNSON BARKER.

Kingsbury House, Lansdowne Road, Worcester,

January 29, 1906.

P.S.—I regret that the prints are not the best examples I have

produced, but I have had no time to make fresh, and cannot recall from loan better ones. They, at any rate, serve to indicate the possibilities of the process which for simplicity and ease is difficult to beat. They must be judged as examples of a process and not on artistic or pictorial grounds.

[We are much obliged to the Rev. Mr. Barker for calling attention to our omission to request examples of the method recommended by him. Three of the six prints have been added to the exhibition. The report to which Mr. Barker refers appeared in our issue of December 1, 1905.—Eds. B.J.P.]

## AN AID TO PRINT-WASHING.

To the Editors.

Gentlemen,—A few weeks ago I read an article in your "Journal" about a "sink." I have a sink here I made, and a description of it may interest your readers and may be of some use to all of them using a sink or tank for washing prints. Fig. 1, A is the sink, B is the waste water outlet. Fig. 1, B, C is a tube fitted into B. When the water rises to top of C it flows down through C and B. A wire-cage on top of C will prevent prints from being carried away, but as this plan only takes the surface water I make a tube, Fig. 2, closed at one end and perforated at the other at least  $\frac{1}{4}$  inch up; this is inverted over C. This then takes the water and channels from the bottom of sink first, and no prints can get away. The water can be left running and the prints washed without watching. To anyone wishing to change the water when washing prints, as so many makers

Fig. 1.

Fig. 2. Fig. 3.

of paper advise, then we can go a step further. I put an air-tight jacket round the tube as in Fig. 3, with a piece of thin wire on top with a hold fast with eye to steady tube, fixed in the wall, the air-tight jacket is just large enough to float the tube as the water rises, the tube is inverted over C as already described. When the water begins to overflow at C a suction takes place and down goes the tube D to the bottom, and the tank or sink is soon emptied, when all the water is gone, as will be noticed by a long gurgling breath. Then the sink begins to fill until the water begins to overflow, then off she goes again, automatically. To prevent the prints from getting in the way the outlet is best placed in the corner of sink, with a wire screen placed diagonally across the corner, leaving room enough for the tube D to work up and down. It could easily be made to register the number of changes the prints have had. D and C can be taken away and a plug put in B as in an ordinary sink.—Yours truly,

JAS. RITCHIE.

Belvedere Studio, Selly Oak.

January 20, 1906.

## THREE-COLOUR BY THE "AUTOTYPE" CARBON PROCESS.

To the Editors.

Gentlemen,—In view of the interest which is being created by the excellent exhibition of three-colour work at your rooms, we venture to think a brief description of the methods by which our two exhibits (Nos. 51 and 51a) are produced, may be welcomed by some of your readers. We are just putting the special tissues and temporary support on the market, and are inclined to think that those desirous of making experiments in three-colour printing will find the carbon process both simple in working and satisfactory in result.—Yours faithfully,

THE AUTOTYPE COMPANY.

74, New Oxford Street, London.

January 29, 1906.

[Pressure on our space this week prevents our printing the notes sent by the Autotype Company, but they will appear at the earliest opportunity.—Eds., B.J.P.]

## Answers to Correspondents.

- \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED :—

- Stuart, Thistlebank, Helensburgh, Dumbartonshire. *Photograph of Dr. J. D. White, Dumbarton.*
- K. Holden, Closeburn, Shrewsbury Road North, Birkenhead. *Photograph entitled, "A Study in Snouts."*
- Hall, The Studio, Witham, Essex. *Photograph of Declaration of Result of Poll for the Malden Division of Essex.*
- A. Kime, 116, St. James' Street, Newport, Isle of Wight. *Photograph of the Declaration of the Poll (Isle of Wight Election) at the Newport Town Hall.*
- Mr. G. Baring, M.P., Addressing the Electors.
- Carson, Komati Poort, Transvaal, South Africa. *Three Photographs of Hippopotami in the Komati River, Transvaal. Photograph of Crocodile and Native Boy in the Komati River.*

**TIME DEVELOPMENT.**—Is there any standard time for developing plates? For instance, if it takes the image, say, one minute to make an appearance, how long before development would be complete? I think I have seen it in print somewhere, but don't know where, if it takes one minute to stamp the image it takes five minutes to complete. I shall be very pleased if you would give me instructions in the "Journal." I may say I am going to use the developer mentioned in your "Journal" of January 5, 1906, page 4. **INFORMATION.**

The system of "time" or factorial development is well known. A lengthy article on it appeared on pages 149 and 168 of the "B.J." last year. The principle as laid down by Mr. Alfred Watkins is that with varied exposure the total time of development for a certain density has a fixed relation to the time of appearance of the image. The total time of development divided by the time of appearance is the factor of the developer, and in developing a plate the duration of development is continued for a time equal to the time of appearance multiplied by the factor of the developer. You will see a paragraph on the subject on page 76 of last week's issue, but you had better get The Watkins Manual (1s.), which treats fully of the system.

**BY MOUNTING.**—On page 846 of the "B.J." Almanac is the following recipe :—Shellac (white), 300 grammes; gum elemi, 30 grammes; Canada balsam, 50 grammes; methylated spirit, 1,000 c.c.s. Is the quantity of shellac correct? If so, will you please say how this is to be dissolved in 333 c.c.s. of S.V.M.?—H. HANNATH.

The formula is correctly quoted from the French author. The alcohol need be divided into three equal parts. Take about three-quarters for the shellac and the rest for the other two resins.

**PROCESS.**—I should be obliged if you would be kind enough to let me know if there is any journal devoted to the interests of lithographic and process reproduction and allied trades; also where I could procure such, if it exists?—ALLAN C. HILL.

The "Photo-Engraver's Monthly" (Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London, E.C.)

**PHOTOGRAPHIC MACHINERY.**—We have seen, at various times, advertisements in your paper of photographic engineers—firms who manufacture coating machines, drying machines, and similar things, but we cannot at the present moment find their names.

We should take it as a great favour if you could very kindly supply to us the name of such a firm.—METTALOID..

Messrs. N. L. Scott and Co., 18, Ironmonger Lane, London, E.C., and Mr. Aug. Koebig, Radebeul Engineering Works, Radebeul, Dresden, Saxony.

**GLAZING PRINTS.**—I beg to thank you for your formula (in last week's "Journal") for glazing prints. I have tried it, but am sorry to say that I have had no success whatever, so I am venturing to write you again, giving particulars. I boiled the shellac with borax as directed, and when thoroughly mixed it became a thick mass of the consistency of treacle, and was, moreover, a dark brown colour. Is this correct? I tried the solution in strengths, varying from one in 1 oz. to equal parts of shellac solution and warm water, but with none of them did I get a trace of glossiness on the cards when dry. The shellac, which was supplied to me as "bleached shellac" was a hard opaque lump of something, which was about the colour of putty. I should be very grateful if you could put me right, as I expect my want of success was due to some fault of my own.

D. O.—We suspect your trouble is due to your being supplied with a sample of lac which has become insoluble by long keeping. The shellac should be freshly bleached, and white in colour. The solution will not be quite colourless, but very nearly so. Better get some lac direct from a lac bleacher—say from such a house as Gedge's, St. John's Street, Clerkenwell.

**THE ROYAL ARMS.**—I note your remarks in the current number of the "Journal" re use of Royal Arms; but can you tell me if I, having had the honour of supplying His Majesty the King with a considerable number of my photographs of this neighbourhood, and of my sea-birds, am at liberty to print on my bill-heads, etc., "Patronised by His Majesty the King," of course, without using the Royal Arms?—C. J. KING.

We know of nothing to prevent you from saying on your bill-heads and the like that you have been patronised by the King, so long as you do not use the Royal Arms in connection with the announcement.

**FINISHING IN COLOURS.**—1. I am making water-colour paintings on platinum matt bromide enlargements. Is there any varnish I could put over the surface to resemble oil paintings? I know it is not a custom to put anything. What effect would paper varnish (clear) have; would it harm the colours? Please let me know what would be best, as I cannot work in oils. 2. In working flesh colours, what colours are best for first wash, and also for finish? Watercolours I am using.—CYMBRO.

1. Varnish with celluloid varnish, and repeat the operation if necessary. Paper varnish would do as a substitute, but is inferior. Either method will increase the brilliance and permanency of the colours. 2. If you wish to imitate oil-colour work, use Naples yellow, burnt sienna, light and Indian red, permanent crimson, etc., and mix as may be required, using a neutral tint with them for shadows.

**A BOOK QUERY.**—I am an old hand at wet plates in the tropics, and, after a little experience of the dry plate, I laid the work aside some years ago. Now, I am settled at home, with plenty of leisure, I want to resume the work. Will you kindly recommend me a good practical up-to-date book which will help me? I find that both in optics and chemistry the world has gone past me, and I want to make up for lost time.—AN OLD SUBSCRIBER.

You cannot do better than "The Science and Practice of Photography," by Chapman Jones, 5s. (Iliffe and Sons, Limited.)

**SPECIMENS.**—I am about to open a studio. I have all apparatus and accessories, but would like to get some nice specimens of carte, cabinet, and larger size photographs. Would you kindly inform me where I could obtain same?—A. W.

Why not make them? A few good portraits of well-known people will be the best window display you can have. As an alternative, we can only suggest that you apply to one or two of the trade enlarging firms, who may be able to let you have framed specimens of their various styles.

**THE RIGHT TO PHOTOGRAPH.**—Enclosed is a postcard of Station Road, Barnt Green, published by us and sold at a agent's in that place; the owner of the house on the left-hand corner of post-

card has written threatening an action against us, and says she can, and will, obtain an injunction to restrain us from selling any more, as she says it is a photo of her house and gardens. Needless to say we had no idea of simply taking her house and gardens, merely wanted it as a view of the road. Please say if we have the right to take and publish it, and if she can legally stop us.—LEWIS BROTHERS.

You are entirely within your rights in making and publishing the photograph. You may refer the lady to the clause in the Copyright Act, which reads:—"Nothing herein contained shall prejudice the right of any person . . . to represent any scene or object, notwithstanding that there may be copyright in some representation of such scene or object." (See paragraph 8 in the "Almanac" article on "Copyright," page 663.)

**SOUTH AFRICA.**—I have been advised, for health reasons, to go to South Africa. Can you tell me the best way to proceed to obtain a berth? Do you know the names of any papers one could advertise in?—S. A.

We know of no South African photographic journals. Vacancies in studios in the colony are usually filled through shippers in London, or by advertisements in our columns.

**W. E. (Grantham).**—We think you will not find a perfectly smokeless flash candle. Your best course, we should say, would be to use the flash in an enclosure in which the smoke would be retained. Better write to Houghtons Limited for particulars of their "Ideal" lamp, which is of this description.

**J. BUSBY.**—Flashlight groups of the same kind as yours have frequently been taken. We think it unlikely that any of the illustrated papers would take it.

**A QUESTION OF PRICE.**—I had a C.D.V. photograph (head and shoulders) of a gentleman brought to me to enlarge to 24 x 20, (sepiabromide) to be finished first-class, and work in background, as the one in photograph was mottled. I quoted 37s. 6d. for it complete. Do you think that too much?—A. C.

The price quoted seems to us to be very low if the work is fairly well done. Of course, you could not produce a very high class picture for the money—that is, if you put the work out to be done by a first-class artist.

**COPYRIGHT.**—As a subscriber to your valuable paper, would you please give me a little information on the following subject? I have taken several pictures of a well-known music-hall artist, and he has given me orders and paid me for same. A picture postcard publisher has offered me a price for copies for reproduction. The music-hall artist will not give me permission to copy-right same. Can he copyright them without my permission, or am I at liberty to sell copies of same to publisher for reproduction, when not copyright, without his (sitter's) permission? Some of my pictures of same artist has been copied and published without my permission or name not being attached in any to same. Is this right?—A. F.

Assuming that the portraits were taken to the sitter's order, and paid for by him, the copyright belongs to him, and he can, of course, register it without your permission. The negatives are yours, whether the sitter registers the copyright in them or not, but you must not sell or otherwise deal with copies from them without his permission. You have been paid for your work, and there is the end of the matter, so far as you are concerned. There is no reason why your name should appear on the reproductions if the sitter did not wish it to do so.

**INTERESTED SUBSCRIBER.**—The stop marked f/11 on the lens mount becomes, approximately f/22, when only one component of the lens is used. This was our reason for saying that you must be working at an aperture at least f/12.5, the full aperture of the lens being f/6.3. In regard to the studio we now see that you have a great deal too much light. We should recommend you to cover the south side with some quite thick calico, and screen also the top and north side. You should adjust the different strengths of the two lightings—the south must be your chief light, unfortunately—until you get a fair amount of contrast in the subject itself. Apparently, you are getting a flat-lighting and trying to make up for this in development. Hence the hardness. The chemicals in the developing formula should dissolve

completely, but will readily separate out if the solution falls much below 60 deg. in temperature. Better stand both in a warm place (70 and 80 degrees F.) for an hour or so, shake at intervals, and then pour off, for use, from any undissolved salts.

**SUBSCRIBER.**—The usual causes of yellowness are: 1. Traces of hypo reaching the prints between toning and fixing: the use of an acid or exhausted toning bath. We presume these are known to you, but we can suggest 10 others.

**INQUIRER.**—Your best course is to become a member of the P.P.A., in virtue of which you can obtain favourable insurance rates. Address the Secretary, 51, Baker Street, W.

**STUDIO QUERIES AND OTHERS.**—In our next.

**QUERIST.**—We do not know of the articles. The late H. P. Robinson wrote a series in the "Practical Photographer" in 1892, under the title "Photography as a business."

**J. N.—1.** We cannot say at present. 2. Extremely unlikely.

**W. SMITH.**—A modified crystoleum process is described on page 851 of the "Almanac," but for full instructions in the usual process you had better obtain the manuals supplied by dealers in crystoleum materials.

**GAS v. Electricity.**—The article from the "Globe," which we printed in our issue of January 12, has brought us from the Gaslight and Coke Company a reply to the advocates of electricity which was published in the "Globe" of the same date as that on which the article appeared in our pages. We have not the space at this date to give in full the arguments of the company, but we can summarise them. It is pointed out on behalf of gas that the "Lancet" Commission appointed to inquire into the sanitary properties of gas fires reported that "gas can be used for warming purposes efficiently without prejudice to health and without the formation of fog-forming or air-contaminating products." Eminent doctors and architects have testified to the innocuous behaviour of gas fires, and the Gas Light and Coke Company point to the number of these sources of heat in the houses of Harley Street physicians and in the homes to which Harley Street sends its clients. The fact that gas consumes oxygen is an argument in its favour, since for every cubic foot of air consumed by a fire, whether of coal or gas, a corresponding volume of fresh air is drawn into the room; whereas, with a non-combustible source of heat like electricity, the want of healthy ventilation is frequently a cause of injury to those occupying the apartments. In the matter of cost, even admitting the excessive percentage of 50 to 60 per cent., as the heat which goes up the chimney from a gas fire, the latter would still be half the cost of electricity at one penny a unit. With gas stoves of the syphon type the relation of cost to electricity at one penny per unit is as 1 to 5. The company concludes: Altogether we view without alarm the competition of electricity as a heating agent; and similarly do we regard its competition in the field of cooking. If it cost the Electrical Exhibition experts 4s. 8d. (that is a sum equal to the cost of a quarter of a ton of coal!)—with current at 1d. per unit—to cook a dinner at Olympia for 65 people, which we should be glad to cook for less than a shillingworth of gas, and 3½d. to cook a breakfast that would not have cost us more than ½d. to cook, there is no need for your readers to sell their gas shares just yet.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The annual general meeting and election of officers of the Royal Photographic Society take place on Tuesday next, February 13. (P. 101).

The first of series of explanatory articles by Mr. C. E. K. Mees, F.Sc., on the methods employed in the scientific testing of photographic plates, appears on page 104.

Colour Photography.—Mr. H. J. Burton, technical expert of the Autotype Company, has drawn up instructions for the preparation of three-colour prints by the carbon process, such as those now being shown in the Exhibition at these offices. (P. 106).

Colour Photography.—The production of prints from three-colour negatives by the "Sinop" process is the subject of practical instruction. (P. 106).

Colour Photography.—A simplified form of the Drac apparatus for colour photography, without filters, has been patented. (P. 111).

Colour Photography.—A camera, with filters of the ratio, 1: 2: 2: 2: for pinachrome-bathed plates, has been introduced. (P. 105).

Colour Photography.—Dyes suitable for printing the three impressions in the Pinatype process have been patented. (P. 110).

Colour Photography.—It is rumoured that the new direct Lumière process will be demonstrated at the July meeting of the Photographic Convention. The aged Ducos Du Hauron is reported to have invented new method of direct colour photography. (P. 102).

A machine for the rapid copying of long lengths of drawings and engravings has been favourably reported on by the Franklin Institute. (P. 108).

A stationer in Shoreditch has been sentenced to two months' hard labour for selling indecent postcards. (P. 117).

Some Postcard Statistics.—During 1904, 2,500 million postcards passed through the offices of Germany, Great Britain, and America. The estimated number for 1905 is 5,000 million. A stationer who, in 1899 was with difficulty induced to buy a thousand assorted picture postcards, is stated to have sold 100,000 in his shop last year. 1,000 picture postcards passed through the Blackpool Post Office during the August Bank Holiday week last year. (P. 108).

## EX CATHEDRA.

### The R.P.S.

The annual general meeting of the Royal Photographic Society will be held on Tuesday next, and by 12 noon on the previous day the balloting papers for the election of officers must be received at 66, Russell Square. In accordance with a time-honoured custom, the president's term of office is for two years, and the Society will thus enjoy the privilege of having Major-General Waterhouse at its head for another year. The fact will be a satisfaction to everyone who has been brought into any relation with General Waterhouse, and it should be equally so to the body of members, who are indebted to an extent they perhaps do not fully appreciate to their president for his unremitting work for the Society, and the tact with which he has occupied a position which has not always been the most pleasant. For the four vice-presidents there are eleven nominations, headed by Sir Wm. Abney and the Earl of Crawford, both of whom by their past services to the Society are reasonably assured of election. Almost all the members nominated for the vice-presidencies are well known by their consistent labours for the welfare of the Society, and the support of any given member will no doubt be considered—as it should be—in the light of the fact that among the vice-presidents to be elected between to-day and Monday next shall be found the president for 1907-8.

\* \* \*

### The R.P.S. Council.

Nomination of a person for election on the Council of the Royal Photographic Society is not to be taken as a proof of that person's fitness for the duties of his office. We know of nominations which have been made without the slightest personal conviction on the part of the nominator that his nominee possesses any of the qualifications which are desirable in the management of a public body. A nominator nominates B because he has seen B's name a good deal in the papers. He thinks B must be a valuable man to be on the Council. It may actually be that he is nominating a man with merely an unlimited capacity of talking: a man who will impede business, and will possibly contribute not one iota to the good government of the Society. A state of things such as this is common in many public bodies, and the moral of it to members of the R.P.S. who may not be in touch with the nominated persons is to assume nothing, but to vote only for those in whom by their own personal knowledge they have confidence. In particular do they need to weigh the purely business qualifications of prospective councillors.

\* \* \*

### The Proposed Exhibition in Paris.

With regard to the proposed international exhibition in Paris this summer, the prospectus of which we published a week or two ago, we hear from various sources

in the French capital that the chances of its coming to a successful issue are somewhat remote. A photographic exhibition of national character has just been opened in Paris, and the support of the trade and the profession has been extremely meagre, the representation of the manufacturers of apparatus and materials amounting to only about five firms. We also have yet to learn that the organisers of the exhibition to be held in July will have the help and patronage of the Photo. Club, or the Société Française, the two important bodies in France which may be said to represent the pictorial and scientific activities of photography. Under these circumstances it seems desirable to wait for further information from the executive of the exhibition before prophesying great things for the event.

### Colour Photography at the Convention.

At the forthcoming Convention to be held at Southampton, in July, a great feature will be made of colour photography. Several processes will be demonstrated during the week, and at one of the evening meetings specimens of all the more important methods will be shown on the screen. Sir Wm. Abney hopes to be present and to show his latest slides. It may be mentioned incidentally that both Messrs. A. and L. Lumière are coming from France especially to take part in the Convention, and there are therefore hopes that the new direct colour process will be demonstrated. The exhibition, which is to be a strong feature of the Southampton Convention, promises to be unusually attractive, and more than half the space has already been allotted.

### The Puff Premature.

Lord Salisbury's dictum, "Verify your references," must no doubt impress members of the Royal Photographic Society as highly desirable of impression on the writer of a paragraph which occurs in the notes on photography in the "Daily Telegraph" of Friday last. It is there stated, with all the verisimilitude of fact, that a demonstration of his new pigment paper was given by Mr. Page Croft at the R.P.S. on the preceding Tuesday. Considering that no such demonstration took place, the testimony of the writer (in regard to the paper) that he "was not surprised to find when exhibited at Russell Square it gave excellent results," must be peculiarly gratifying to those who espouse the cause of the gum-bichromate process. The incident appears the more regrettable in the columns of a journal which has stood out against the unconfirmed publication of sensational "news," and not long ago vindicated the authenticity of its early intelligence.

### Snap Shots in the Studio.

One of our contemporaries last week printed a paragraph referring to the published statement that M. Lafayette has perfected an arrangement for taking portraits of children in an artificial-light studio with the very short exposure of a twenty-fifth of a second. After briefly describing the type of camera employed, the writer goes on to remark that the exposure of one twenty-fifth of a second by artificial light may seem a stretch of the imagination, but that by bathing a plate in the pinachrome dye solution a speed of 500 H. and D. may be obtained working in artificial light, and that with such a plate Mr. Arthur Payne has photographed stage scenes with ordinary stage lighting in one-eighth of a second, using a lens at  $f/4$ . It is, of course, possible to demonstrate a thing which may be impracticable in everyday work, and we believe the particular photograph referred to required quite abnormal treatment in the dark-room,

the development being prolonged and carried out with a solution at a temperature only a little below that at which the gelatine would have melted. Under such circumstances a granular image was probably produced, and the exhibited half-plate print had, we think, been enlarged, rough paper being used to hide the grain. We do not criticise this production, which was in some ways a tour de force, but it should be noted that the bathed plate used showed the high speed to an artificial light of a yellow tinge, and was employed under the conditions for that express reason. When seeking to cut down the exposure in the studio, we think the most practical method is to use an ordinary plate of extreme rapidity and a light rich in the violet and ultra-violet rays. Such an illuminant is much less trying to the eyes than a more yellow light, and though it brings out the freckles, the retoucher is quite able to deal with them afterwards. With a Westminster enclosed arc-lamp an exposure of one twenty-fifth of a second at  $f/3$  on a 300 H. and D. plate is quite practicable, and there is no reason why such work as snapshots of children in the studio should not be done on small plates with a lens working at  $f/2$ , the picture being afterwards enlarged to cabinet size.

### Variety in

### Backgrounds.

Insufficient attention, we think, is paid to the variation of the background in many studios, and though we do not suggest that new backgrounds should be purchased every month or two, much more might be done to vary the effect produced by the same background. The difference, for instance, between the ground turned to the light and away from the light will be very considerable, and if mounted on a square frame such an alteration in position is easily made. A reasonable length of studio is necessary to allow for the oblique position, and also for a further variation of effect which may be produced by placing the background nearer to or further from the sitter. Still further differences may be introduced by throwing a shadow on a portion of the ground. An effective method of doing this is by placing a wing at the side of the background, attached thereto by hinges, which may be adjusted to throw more or less shadow across the ground. The shadow produced in this way will darken that side of the background behind the lighted side of the head or figure. Apart from the ordinary painted ground, however, a good deal of variety may be obtained in portraits by the use of draperies, either plain or figured. The way in which a fabric is suspended will produce many differences of light and shade. In selecting materials care should be taken to choose something which will fall into graceful folds, and there is nothing of more all-round usefulness than plain woollen serge. If a fabric with a pattern is employed, the design should be somewhat formal, and depend for its effect on the decorative line or form rather than on colour, which, of course, is lost in the photograph. The principal difficulty in selecting will be to find something with very subdued contrast, so that the pattern is only suggested in the portrait. The photographic effect of colours must be borne in mind. Materials with a design thereon will be more effective in use if being with only slight folds, the pattern itself being relied on for relief.

COLOUR Photography.—Rumour has it that Louis Ducos du Hauron, the gifted inventor and originator of colour photography in various of its present-day aspects, has devised and worked out a system of direct photography in colours which embodies the wished reduction to simplicity, so many times announced but so long in realisation. We state the rumour merely as it reaches us from a private source in France, but we have no means at present of subjecting it to verification.

## PRINTING PROCESSES.

XVIII.—CARBON (*continued*\*).

In continuation of our previous notes, we may now proceed to emphasise some points on the exposure and development of carbon prints, in regard to which some uncertainty is often felt by those inexperienced in the process.

It may be as well to explain here that the most suitable negatives for carbon printing are those of a vigorous character, such as yield the best results on albumen paper, or by the platinotype process. Other types of negatives may be employed and yet give excellent prints, but with such it is advantageous to sensitise tissue specially to suit them. That is a point that will be dealt with later on. For the present we are assuming that the ready-sensitised tissue of commerce is being employed, and for this vigorous negatives are the most suitable.

Carbon tissue affording no visible image, we require some sort of guide as to the exposure. There are several forms of actinometers for the purpose on the market, ranging in price from a shilling upward. They are all good, but the most convenient in use are those with a graduated scale of tints. With those dependent upon a single tint, when that depth of tint has passed, it is difficult to estimate how much it has been exceeded: with the graduated number scale, however, there is no such trouble. A strip of P.O.P. is used in the actinometer, and it will be well to always employ the same brand of paper, because different makes vary somewhat in sensitiveness, and a change of paper may lead to errors in exposure. The following is a simple method of arriving at the necessary exposure, supposing the worker has had no previous experience in the carbon process. Select a couple of negatives of similar density and put them in printing-frames. Behind one put a piece of carbon tissue, and behind the other a piece of the same P.O.P. as that placed into the actinometer. Expose three to the light until the P.O.P. print has become nearly as dark as it would be desired to be after it had been fixed, fixed, and dried. Now note the number shown by the actinometer and develop the carbon print. If the exposure turns out to be correct we know that all negatives of density similar to the one used will require the same number of tints—supposing the same brand of P.O.P. be used in the actinometer. Should the print prove to be under- or over-exposed, more or less tints are required. With a very little experience even a beginner in the carbon process will be able to judge at a glance the exposure necessary for negatives of various densities. After there is, in carbon printing, such a latitude allowed that a picture need rarely, if ever, be lost through errors in exposure.

There are, as everyone knows, two methods of working the carbon process—the single and the double transfer. The former, unless the negative be a laterally reversed one, will yield prints that are reversed as regards right and left. Here a large number of prints have to be made it will be better to make reversed negatives, or to take them in the first instance on a celluloid film which can, of course, be developed from either side. An extra operation, namely, the transferring of the picture from a temporary support on which it is developed to a permanent one, is thus avoided. As the manipulatory details are exactly the same in the two systems, we shall here describe them as applied to the single transfer, which the novice is advised to begin with. After the exposed print is taken out of the frame, together with a piece of single transfer paper a little

larger than the tissue, is put into a tray of cold water. The tissue, by reason of the paper absorbing water quickly, and expanding before the gelatine does, will curl up, face inwards. In a very short time, however, as the gelatine absorbs water it will flatten out again. If left longer it will curl up face outward owing to the gelatine expanding more than the paper. As soon, however, as the tissue becomes flat, or a little before, the face of the tissue and that of the transfer paper are brought into contact under the water and removed; tissue upward, on to a sheet of glass or other flat surface and squeegeed together, a flat, or scraper, squeegee being used for the purpose. The prints are then put between blotting paper, or, better, blotting boards, and allowed to remain for ten minutes or a quarter of an hour, when they will be ready for development. Text-books usually say put the prints under pressure as well as between the blotting paper, but that is quite unnecessary, and is never done by professional workers. The blotting paper, or boards, absorb any superfluous water that may be on the backs of the pictures, and that is all that is required.

Most persons have, doubtless, witnessed demonstrations of the carbon process, but a word here may not be out of place with regard to the application of the squeegee. When the print and paper are laid on the plate the tissue should be pressed firmly in contact at one end with a couple of fingers, say, of the left hand, the squeegee being in the right. The squeegee is then passed slowly, and with somewhat heavy pressure, over the print from left to right, commencing the stroke about one-fourth from the end. Then a similar stroke is made from right to left. If the work be neatly done, one stroke each way is quite sufficient, though more squeegeeing does no actual harm. In this way all risk of air bells being imprisoned between the tissue and the transfer paper, which would eventuate in blisters, is avoided.

After the mounted prints have rested for the requisite time, two or three are put into water at a temperature of about 95 deg. Fahr. In a few minutes the gelatinous coating of the tissue will begin to dissolve, and will be seen exuding from the edges. A corner of the tissue is then raised, and the two papers gently separated under the water. The print is then turned face downward. Others are then dealt with in the same way, though the novice will do well to deal with only one or two at a time. When the prints have remained for a minute or two they are turned over and examined. If on lavage the water over them a few times the high-lights show strongly before the shadows begin to clear from the unaltered gelatine it is an indication that the print has had an insufficient exposure. Still, it need not be lost—unless very much under-exposed—if it be immediately put into cooler water, say at 80 deg. Fahr., and the development allowed to go on in that. If the picture is seen to clear about equally in the lights and shadows the exposure has been about right. If, when the lights and shadows are both cleared of the unaltered gelatine, the picture is still too dark, it shows that the exposure has been more or less too long. Still it will yield a good result. In this case the temperature of the water should be increased to, say, 120 deg. Fahr., and in extreme cases of over-exposure it may be increased to 140 deg. or more, but the use of water so hot as that is not to be recommended, as the same end—general reduction—can be attained by longer soaking in water of a more moderate temperature, say, about 125 deg. The longer the picture is left in warm water the more it becomes reduced, so that the reduction is only a question of time. It should be kept in mind during the development that all carbon prints dry up somewhat darker than they appear while in the wet state.

\*The previous article on carbon appeared in the "R.J." of Jan. 12. The processes dealt with in this series of articles are plain salted paper, albumen, bromide gaslight.

There is one point in connection with the printing of carbon tissue that should be noted. The tissue gains in sensitiveness by keeping. Therefore, if it has been sensitised for some days it should receive rather less exposure in printing than if it had been used when it was freshly prepared. When the development is completed—that is, when the print is cleared from all the unaltered gelatine

and is generally light enough—it is rinsed in cold water and then put into a solution of alum—strength immaterial—until the yellow tint on the paper is removed. After rinsing in water to remove the alum the picture is finished. In the development of carbon pictures there is great scope for local treatment, but that will be dealt with in a future article.

## THE INTERPRETATION OF SENSITOMETRIC TESTS.

### I.

[The figures given during the course of last-year in specification of the properties of new gelatine plates, which were submitted to the BRITISH JOURNAL OF PHOTOGRAPHY for review, have been, so we hear, much appreciated by a number of more scientific workers, but were probably of very little value to the great majority to whom mathematical expressions are a strange language. The following short series of articles has therefore been written by Mr. C. E. Kenneth Mees with the desire to familiarise others with the meaning of the various properties of a plate. The first article is devoted to certain general questions of sensitometry. The second will deal with the "inertia" of a plate and plate speed-numbers, and the third will consider the developing, orthochromatic and other properties of a plate and will give some specifications of plates suitable for various purposes.—Eds., B.J.P.]

### The Purpose of Sensitometry.

FROM the earliest days of photography a need has been felt for some method of expressing the relative sensitiveness of the materials employed. There is no necessity here for tracing the historical development of those methods which are at present in use, but it would be desirable to make clear at the outset that there are two entirely different points of view to be considered. They are those of the maker of the materials, and of the user of those materials. In order that a plate-making works shall run as efficiently and economically as possible, it is desirable that the manager shall be able to detect the smallest possible variation in the products. The real problem before plate-makers to-day is not increase of sensitiveness or lowering of price, but reliability; and unfortunately, owing mainly to the apparently inaccurate methods by which gelatine is made, reliability is extremely difficult of attainment.

This is the reason why the larger plate-making firms are willing to spend large sums of money on accurate testing apparatus, and to test not merely their own products, but those of their commercial rivals.

This appears to me to be the real reason, and the only reason, apart from theoretical science, for the development of accurate methods of investigating photographic plates, reliability in manufacture can only be obtained by the use of accurate testing methods. The cause, e.g., as it seems to me, of the great variations in sensitiveness displayed by commercial orthochromatic plates is that there is really no satisfactory and accurate method of testing the colour sensitiveness of a plate which is in general use, the usual method being to employ either a spectrograph, or some form of colour sensitometer, and to judge the result by eye—a distinctly inaccurate method.

### The Sufficiency of Inaccurate Sensitometry.

From the point of view of the user the aspect of affairs is entirely different. The limit of accuracy necessary here is conditioned by the method of checking used, that is by the practical employment of the plate. Almost every practical photographer is aware that it makes no sort of difference to the result whether he exposes a plate for two or for three seconds—most of us know the gentleman who calculates an exposure with a meter with great care, finds it to be 1.5075 of a second, and then adds a second "for luck." Consequently an accuracy of 50 per cent. is quite sufficient in testing for sensitiveness as far as the user is concerned. When one deals with the developing properties of a plate, however, the eye is a much better

judge. There is a considerable difference in gradation between a development factor of 1.0 and one of 1.4, and a plate with limiting factor of 3.0 is visibly superior to one with a factor of 2.5, so that here an accuracy of, say, 20 per cent. will be desirable. Fortunately it is a comparatively easy matter to express the developing properties of plates numerically in such a manner that they may be practically utilised: to express the sensitiveness in the same way would be almost impossible, even if it were desirable. In fact, the sensitiveness of a plate is a complicated function that the relative sensitiveness of two plates can only be *accurately* compared, with respect to a light source, working at a fixed intensity. But a very considerable accuracy can be obtained under much less stringent conditions.

### Speed and Light Variations.

The two respects in which light sources vary are:—

- (i) Their colour.
- (ii) Their intensity.

For example, suppose that we are using two plates, one of which is only sensitive to the blue, while the other is only sensitive to the yellow, and that they have proved to be of equal sensitiveness when measured by mid-day June cloud-light, and we wish to use them for taking a portrait by incandescent electric light containing twenty times as much yellow as compared with blue as the cloud-light did; then it is clear that instead of being of equal sensitiveness, the yellow-sensitive plate will be twenty times as sensitive as the blue plate.

But these conditions are very extreme indeed. The variations in colour-sensitiveness of ordinary unorthochromatic plates are practically negligible, while the best commercial orthochromatic plates are still about six times as sensitive to blue as to yellow.\* Moreover, most plates are used under fairly constant conditions as regards lighting; the variation in spectral composition of daylight is comparatively small.

So that under normal conditions the error in sensitiveness due to colour variation is with ordinary plates negligible, and may amount to 20 per cent. with good orthochromatic plates.

Of course the sensitiveness of plates must be compared with the light which is to be used, if an ordinary and an orthochromatic plate are compared with, say, candle-light, and then with daylight, very big discrepancies may become manifest, this is an avoidable error.

Besides their variation in spectral composition, light sources also vary in intensity. It was shown first by Sir William Abney that if a plate was exposed

\* Neglecting bathed plates, in which the yellow and blue may be nearly equal in sensitiveness (daylight tested).

second to a light source, and then 100 seconds the same source, removed to such a distance that it is only 1-100th of the original intensity, then the same effect could not be obtained. Consequently, if we have two plates, one of which requires 1-10th of the exposure of the other at 4 in bright sunlight, then if we took a photograph in a building such that the fast plate requires one hour exposure, the slow plate may require not ten hours, but possibly twenty hours.

But it will be seen that this again is a very extreme case, and could scarcely occur in practice. I have found, for instance, with a Wratten ordinary plate that the error due to this cause is not so great as was supposed. The error then would be about 2 per cent., so that we may neglect this error.

We see, then, that if we use ordinary plates we can trust the measurements made of their sensitiveness for use in practical work, while if we use orthochromatic plates under widely divergent conditions, we may obtain differences amounting to as much as 20 per cent., and possibly by deliberately choosing conditions even more.

But I think, as I have said, that we do not in practical work get our exposures right to 50 per cent., and consequently need not worry about these errors. In the case of the plate-maker the question is quite a different one, he wants accuracy to 5, or even 2, per cent. if possible, and since what he wants to know is not usually the ratio of two different plates for practical work, but variations in the same plate, in order to promptly detect errors in manufacture, he can always use the same light-source under the same conditions. So that the accuracy he can obtain is independent of the considerations which limit the use of the tests in practical work, and is conditioned by experimental errors only.

This is not the place to discuss the extent of those experimental errors. With regard to sensitiveness determinations, the chief error appears to be in the difficulty of coating a plate accurately. Even with the use of patent plate the errors from this source outweigh all other experimental errors, while if ordinary commercial plates be used the coating errors may be 14 per cent., or even more. In the case of development factors the possible sources of error are far more numerous.

C. E. KENNETH MEES.

## COLOUR PHOTOGRAPHY.

### THE PINATYPE CAMERA.

My notes upon the Colour Exhibition now open at the offices of the B.J., I referred to a set of new screens for three-colour work, with which the exposures were as 1:2:2: for the blue, green, and red respectively. These are fitted in

in which the colour filters are carried. This is actuated by a pneumatic release. The plates are carried in single metal slides, and the shutters of all three slides are withdrawn. The exposure having been made through the red filter, the pneumatic bulb is sharply pressed; and the frame carrying the colour filter drops, bringing the plate behind the blue filter into position for exposure; then the bulb is again pressed, and the frame drops, bringing the plate behind the green filter into position.

The rate at which the change is effected can be altered by the small screw shown at the bottom of the frame on the right. The time taken to change from one filter to another, of course, varies, but the average seems to be about two-fifths of a second.

The repeating back, which is stoutly made of wood and black metal, weighs about 2½ lb., and measures 8 in. by 21 in., and can be hooked on and off the camera, so that the latter can be used for ordinary work. It may also be obtained as a separate fitting, and can then be adapted to any camera with front focussing movement, for obviously it must project above and below the camera top and bed. Three of the metal dark slides weigh, unfilled, 9½ oz. These weights and measurements apply to the 9 by 12 cm. size.

The ratio of 1:2:2 applies only to pinachrome bathed plates, but still this is, I think, a big advance. The camera with fittings is supplied by Fuerst Bros., who also supply these "rapid-filters." Taking the old filters, such as were recommended by Dr. König—who gave the formulæ for them—the ratios with the same plate were 1:4:3, or a total of 8, so that we have a reduction in the total exposures of from 32 to 20, for the blue-violet filter requires an increase in exposure of four times for the same plate unscreened. With the new filters focussing is effected in the usual way, through the red filter, which is the most brilliant of the three. I have not yet had time, nor sufficient sunlight, to determine the absorption of these filters, but there is obviously overlapping in the yellow and blue. From a private communication from Dr. König, I gather that these new "rapid filters" are made with some special new and pure dyes which he has discovered.

E. J. WALL.

new camera, a description of which may possibly be of interest to the readers of the B.J.

The special feature about the camera is the repeating back

### THREE-COLOUR PRINTS ON "AUTOTYPE" TRICHROME TISSUES.

The following is the official description of the method employed in making the two exhibits, Nos. 51 and 51A in the Exhibition of Colour Photography. These three-colour prints, which are excellent examples of trichromy by the carbon process, are on the newly-introduced trichrome tissues of the Autotype Company, to whom we are indebted for placing at our disposal an account of the *modus operandi*. The tri-colour tissues, we may add, have been brought to their present state of readiness for the market by Mr. H. J. Burton, who, for upwards of thirty years, has been connected with the Autotype Company, and for many years its chief technical expert.—Eds., B.J.P.

The brief general principle of this process is as follows:—Negatives of coloured objects are taken on special colour-sensitive plates, which are used with light-filters or screens, by known methods. The negatives are printed on carbon tissues of suitable red, blue, and yellow pigments. The resulting images are then developed and superimposed on one support. To those familiar with the working of double transfer carbon, the process now described will present little difficulty. The tissues, yellow, red and blue are sensitised, dried and printed in the ordinary way, the negatives being provided with safe edges.

The exposure differs somewhat from the ordinary carbon printing, and as the negatives are usually very thin, the exposure is rapid. In our experience we have found the following to be the approximate ratio of exposure:—Blue, 2; red, 3; and yellow, 8.

After exposure the prints are squeezed on special semi-transparent temporary support, and developed in water of about 95 degrees to 100 degrees Fahr. After development they are rinsed in cold water and hung up to dry.

The most suitable support for the final transfer of the prints has from experience been found to be ordinary *single* transfer paper. The pieces of this it is intended to use should be placed in cold water for about half-an-hour, and then immediately before use into hot water about 140 degrees Fahr. for about quarter of an hour. When ready, take a sheet of this paper and place in a dish of cold water and immerse the yellow print at the same time. Place the yellow print face to face with the transfer paper under water, lift both out

together, and hang up to dry. It is not necessary to use a squeegee. When the print has become dry raise the support at one corner with a pin or sharp knife, and then run a paper knife between the two to separate them. The yellow print having been successfully transferred the next step is taken with the red one.

Before attempting to transfer the red print, it is necessary to remove from the yellow print every trace of the waxing solution. This is done by rubbing the print over with a piece of rag wetted with benzole and a little tripoli or whiting. Both the red and blue prints are transferred in the same manner, but a transfer solution (see below) is required to ensure adherence.

The yellow print resting on its final support is immersed in clean cold water, and, when flat, is laid in the transfer solution face upwards. Soak the red print in cold water and place that also in the solution face downwards upon the yellow print, avoiding air-bells. Lift both out together and lay them upon a sheet of glass. The semi-transparent nature of the temporary support allows the prints to be easily examined by transmitted light, and the registration of the superimposed images is easily effected. The images resting on the glass are now stood on one side to drain, the two being then detached from the glass and hung up to dry.

The transfer of the third or blue print is accomplished in exactly the same manner, including the treatment with benzole, etc.

No alum or other hardening substance should be used until the final print has been transferred, then the compound picture may be placed in a very weak solution of formaline.

Absolute accuracy of registration is facilitated by placing on the negatives at diagonal points two tiny black dots, which will appear white in the resulting prints. These white spots are pierced with a needle on the dry prints and brought together during the transfers. If they fit together accurately, it may be assumed that the registration is correct.

The transfer solution is compounded as follows:—Nelson's No. 1 cut gelatine, 1 oz. to 60 oz. of water. It is strained before use and employed at a temperature not over 90 degrees Fahr.

### THREE-COLOUR PRINTING

AMONG the variety of processes which are being used by three-colour workers for the production of prints collotype is almost universally passed over, first because it savours of the mechanical among processes, and secondly because it seems difficult to acquire and unreliable in results. Undoubtedly the old collotype process is a complicated affair and requires working on a large scale to obtain regularity, but with the advent of Sinop emulsion and ready-coated plates, with their smooth free-inking properties, the inherent difficulties of the process are overcome. The emulsion, which is of a whitish hue, is so much more tractable than ordinary gelatine, being so easily brought into condition, by means, in principle, the same as ordinary collotype, that any amateur who is capable of making his three-colour negatives need have no hesitation in adopting it, and so have the satisfaction of being able to see the results of his negatives both in printing ink and pigmented films. Turning to the consideration of the technical details involved, we come to first:—

#### The Preparation of the Negatives.

No doubt collodion emulsion is theoretically preferable, on account of its truer rendering of the curves of sensitiveness, but on account of its longer exposures, and the fact that dry plates are easily obtainable, it is very seldom used. Lumière's "C," Cadet's "Spectrum," "Gem Tricol," are panchromatic in character, requiring only the use of suitable filters to cut off the rays not required. The colour filters must, however, be properly adjusted to these plates, otherwise one or other of the colours will always be predominating. Mr. H. O. Klein, Messrs. Sanger Shepherd, and Dr. Miethe supply filters adapted to each brand of plate. In this connection it is important to find out by experiment the exact ratio of exposure for each of the negatives, for all should develop up to the same density, and if the development of one or other is unduly prolonged, it means the production of a negative false in character to the others, and so spoiling the completed picture.

#### Retouching.

While any retouching whatever is an acknowledgment that we have failed to reproduce the colour sensations correctly, still a little must be allowed in certain cases, say in those parts which we know should

### BY THE SINOP PROCESS.

print white, but owing to the general softness of the negative apt to tone over. And, again, in case where brilliant greens and violets should appear, and we know our printing inks, not being theoretically correct, will render them degraded, a little touching on the red and yellow printing negatives may surely be allowed. The negatives for Sinop printing must not, however, be dense or clogged up; must give an equal rendering of the grey scale, and must, in fact, be a specially even set, as there is no dodging that can be done to help them when once the "Sinop" plate is made.

#### Preparation of the Plates.

The preparation of the plate is identical with that for monochrome printing, but as this is little known we will give a brief outline. The packets of plates as they are sent out by the makers with the necessary instructions are insensitive, and will keep indefinitely. It is only after they are sensitised and dried that their comparative freshness or staleness needs considering. In drying the plates in the light-drying-box provided the usual mistake is to dry them at too high a temperature, so that the coating melts and runs unevenly on the plate. To avoid this, level the box and prop open the gauze-covered lid a little. It is as well to put a thermometer in the box while drying the first few, to see the temperature keeps about 110 degrees Fahr. When the plates are dry withdraw the lamp and let them cool down, but wait till they are cold before placing face to face.

If placed face to face while hot, or even warm, the film will split off the glass. They should have a smooth, glossy, bright yellow appearance; if exposed to damp they will turn matt and become insoluble. The plates are now in their most sensitive condition, and will become slower day by day, till at the end of about a week it would be better to make fresh ones.

So far the operations for preparing the plates are identical with one-colour printing. Having prepared the plates, we will now consider the preparation of the three negatives for them.

#### Printing from the Negatives.

One of the advantages of "Sinop" is the possibility of procuring clean white margins, and as these add greatly to the appearance of the print a word or two of direction should be useful.

If the negatives are films, a great deal of trouble is avoided, as is only necessary to superimpose two of them exactly, and prick rough with a needle at the four corners, and then repeat the same with the third; but in the case of glass negatives, after marking the four corners of one, it is necessary either to measure from some finite object visible in all three, or to make a film transparency from the marked negative and superimpose as before.

Now take strips of thinnest tinfoil, moisten slightly on the lips, and mask round the negative; do not use gum of any sort, as it prevents absolute contact. The correct exposure in the printing frame is a matter of experience. Some prefer to use an actinometer, but to judge from the appearance of the plate looking through the back when it becomes easy. The plate should be exposed till the image is all out, but no more; to expose till there is any depth in the shadows is fatal. One important point which has never been previously mentioned is the temperature of the water in which the plates are washed. In the winter, when the water is very cold, the plates dry with high-lights decidedly glossy, and the prints have a bold, almost hard appearance. In the summer, when the water is often 70 degrees and over, they dry with a visible grain, and give very soft prints, so that it is advisable to reduce the temperature with a little ice to somewhere about 55 degrees Fahr.; this will ensure getting the same class image all the year round.

A properly exposed plate when washed out and dried should have at the extreme high lights glossy; all the rest of the plate should have the appearance of a very fine engraving.

#### Printing from the Plates.

We now come to the "setting up" of the plates in succession on the colour bed-plate. As far as the actual settling of the plate upon the bed-plate is concerned, the instructions in the booklets are clearly and easily carried out, but for three-colour work we must have a pile of paper cut by guillotine to ensure regularity of lay. The actual rolling up of the plate seems to be the operation which all novices fear; they will not master, and becoming bewildered by the behaviour of the rollers which are strange to their handling they give up in despair soon. Let us consider the elementary principle on which the image is formed. It consists, as far as the plate is concerned, in gelatine hardened more or less by the action of light. It follows, then, that when the glycerine solution is placed on this, the slightly hardened gelatine will absorb it and become wet, while those more hardened will remain dry, so that when the plate is mopped up, and the roller applied, ink will adhere to the dry parts and not to the wet, so that the image is formed. Consequently, when the plate rolls up too dark, more water should be added to the glycerine, and further soaking is required. If the plate seems too wet, dry in gentle warmth, and add more glycerine. Similarly with the rolling up. By rolling fast you take off the ink, or by rolling slowly you can make the faintest image ink heavily. Lift the roller after each stroke so as not to have the same surface passing over the same part of the plate every time. On passing through this admittedly trying time for an amateur do not waste temper and energy unnecessarily, and, above all, do not lose time in trying to get a good print from a plate which you know is not good. Far better wait patiently till you have another ready. In printing from the yellow plate it is a good plan to examine the prints through the violet filter, when the image will appear as a black; it is then much easier to judge its comparative strength. The greatest care should be taken to lay the sheets of paper close up to the gauge points, as the least variation will show in the finished print as badly as similar mistakes in the red and blue printings.

The accompanying sketch shows the bed-plate, with the mask slightly raised, and the sheet in position. The gauges should be moved up so as to be just stiffly movable.

As there is sure to be a number of accidents, etc., in the three

#### THE EXHIBITION OF COLOUR-PHOTOGRAPHY.

We may remind those who may not already have visited the exhibition, that it remains open until March 3 from 10.30 to 4.30, daily, except Saturdays, when the hours are 10.30 to 12.30. At the time of writing some 500 ladies and gentlemen have paid a visit to the exhibition, and the attendance shows no signs of diminishing. On the contrary, there is evidence that many visitors are the cause of the exhibition becoming known among those who may be assumed to be outside the circle reached in the ordinary way by the photographic Press.

printings, it is as well to do enough yellow prints to allow for contingencies. For instance, if fifty yellow prints are done, to finish up with twenty completed good prints is not a bad average. After

the number of yellow prints are done several more should be printed in black ink. These are for use in getting correct register with both the red and blue printing plate.

#### Registration.

Having replaced the yellow plate with the red one, as soon as the plate is in sufficient condition to give a good print pull a print on one of the black prints, and, judging from the amount it is out of register, so alter the gauges accordingly. Then print another and another, until perfect register has been obtained; this will probably use up about six of the black prints. When it becomes necessary to move the gauges an almost imperceptible fraction, the mask should be marked round at the head of the gauges with pen or pencil, when the least movement will be readily perceived. Care should be taken to keep the red prints as even as possible. This is the most difficult colour to print with, and if they are allowed to vary much, the completed prints will vary still more when the blue is added. In fact, this difficulty of obtaining even prints is the main obstacle to be overcome. Both the yellow and the red printing inks at present in use are not so easy to manipulate as ordinary black. The blue ink presents no special difficulties, hence the necessity for preserving even printing during the yellow and red colourings. It is important also to remember that each printing is but a third of the completed picture, and so avoid getting the yellow and red prints too strong or heavy, or the completed picture will have a crude appearance.

After each printing the prints must be left overnight to dry, otherwise the wet ink of the print will set off on the plate, leaving the print with a mottled appearance.

The makers of colour inks are striving to produce inks theoretically correct and also permanent. The red ink seems to be the least perfect, but there are several reds to be obtained which, while not absolutely permanent, are sufficiently so to outlast the interest any prints done with them may create.

The density of the inks must also be taken into consideration, so that the yellow being the bottom colour should be printed fairly strong, in order to take its proper place in the composition of the picture.

In conclusion, while no doubt a little patience is necessary to acquire the requisite skill in rolling up the plates, the other advantages of the process are well worth considering. The softness of gradation, the brilliancy of colouring, the ability to print on almost any kind of paper, and produce almost any desired effect, all tell greatly in its favour. The writer has himself produced numbers of prints in the way here described which have been greatly admired by such experts as have seen them.

S. G. YERBURY.

Among those whose names are to be found in the visitors' book since we last inspected it, may be mentioned:—Geo. Bankart, Lady Lockyer, T. Sebastian Davis, T. C. Turner, Major-General Waterhouse, H. J. Burton, C. G. Zander, H. H. O'Farrell, F. T. Corkett, C. Phipps Lucas, W. Saville Kent, H. Holcroft, Dr. Albert Norman, William Grove, F. F. Hollyer, W. E. Brewerton, Dr. B. Jumeaux, J. T. Ashby, J. W. Marchant, J. A. C. Branfil, F. A. Bridge, J. Turnbull, Dr. W. H. Perkin, F.R.S.

## PICTURE POSTCARDS.

In the course of a lecture delivered before the Bolt Court School of Photo-Engraving on Thursday in last week, Mr. F. T. Corkett, of Messrs. Raphael Tuck, brought forward a number of facts and experiences of the postcard publishing trade, the repetition of which cannot fail to be of interest to photographers and others who may be regarded as providers of the raw pictorial material from which, to a very large extent, the postcard maker works.

### The History of the Picture Postcard.

The first picture postcard, it appears, was produced about 1870 by a French stationer in commemoration of a visit of a regiment to the town in which the stationer resided. Until 1894 no picture postcards were issued in Great Britain, the postal regulations forbidding the issue of any printed postcards other than the official ones. In fact, the first picture postcard to be issued in Great Britain was an official halfpenny card published in commemoration of the Naval Exhibition of 1891. It bore an impression of the Eddystone lighthouse, a model of which was erected in the exhibition. In 1894 three British firms only were in the business. In 1899 the Post Office authorised a card of  $5\frac{1}{2}$  by  $3\frac{1}{2}$  inches, a concession which at once gave an impetus to the postcard trade which had already assumed fairly large dimensions on the Continent.

### Postcard Facts and Figures.

As instancing the enormous strides which the sale of postcards had taken, Mr. Corkett compared the difficulty of getting a stationer in a South Coast resort to take into stock 1,000 cards. That was in 1899. Last summer the same stationer confessed to having disposed of 100,000 cards in the course of a year.

In the Postal Union returns for 1903, the entry against Great Britain is for no less than 613 million postcards, three-quarters of which it is estimated, or 450 million, were of the picture variety.

A census of the postcards passing through this office was taken last year by the Blackpool postmaster during the holiday season (July and August), from which it was found that an average of

215,000 picture postcards *per week* were despatched from Blackpool during the period, while in one week (the first week in August), as many as 300,000 picture postcards were posted.

It is estimated that two-thirds of the postcards published in Great Britain are views and of photographic origin. Just at present there is also a wave of popularity for the bromide card of actresses' portraits, and the output of one firm who specialize in this line has been estimated at 1,000,000 per week, equivalent to 20,000 yards of sensitive material 34 inches wide.

During 1904 over 2,500 million postcards went through the post in Germany, Great Britain and America alone. The figures for 1905 are not yet available, but it is anticipated that the total for these three countries will reach nearly 5,000 million.

### The Future of the Postcard Industry.

Mr. Corkett took no pessimistic view of the future of the picture postcard. The prosperity and permanency of the industry, he strongly felt, were dependent on the supply of a good article, which did not transgress the laws of decency. There was little demand for cards which were technically poor and vulgar in subject. Their presence in the trade was, nevertheless, a menace to the growth of the business, and stationers and all dealers in postcards could not be cautioned too seriously to taboo them utterly. Once the mind of the public became prejudiced against the postcard all efforts to acquit it of the charge of vulgarity would be fruitless, and the end of its prosperity would inevitably follow.

### Subjects for Postcards.

Mr. Corkett's position as studio manager and reproductive expert of Raphael Tucks gives authority to his advice on the submission of photographs and other originals for publication as postcards. "Have some definite object in view. Specialize some particular line of objects, but do not fly from landscape to portraiture, from animal studies to flower prints, from breaking waves to cloud effects. Remember the publisher requires a set of six similar designs to a series of subjects. They (the six photographs) should be consecutive, and should convey something as a homogeneous whole."

## A MACHINE FOR PHOTO-COPIES OF LONG TRACINGS.

A COMMITTEE of the Franklin Institute, Philadelphia, has reported on a machine, the invention of a Professor L. F. Rondinella, by which tracings up to 70 ft. in length are printed on sensitive papers, such as ferro-prussiate and ferro-gallic. The adjustments of the machine, which appear to be provided very satisfactorily, are for the printing of short as well as of long tracings, and for the correct exposure of papers of different degrees of sensitiveness. The committee, of which Mr. Louis E. Levy was the chairman, has recommended the machine for the award of the John Scott Premium and Medal, which is within the gift of a Committee of Science and the Arts of the Franklin Institute. The following extract from the report explains the construction of the machine.

The form of the apparatus under present consideration, to which the inventor has given the name of "Star Photo-Printing Machine," is designed especially for the practice of the blue-print and paper-negative processes, and was patented March 19, 1901, No. 670,349. The machine is adapted to print by sunlight or artificial light as may be most convenient, and accordingly comprises two independent parts, the printing machine proper and the electric lighting apparatus upon which it is supported.

The printing mechanism is contained in a casing which is provided with ball casters so as to be easily rolled out from its support upon tracks arranged for the purpose through a window for sun-printing. The casing is made of well-finished oak, and contains all the requisite materials of the printing process throughout, and also all the mechanism of the apparatus except the small electric driving motor and its reducing gears. These are fixed on the exterior on one side of the machine. The casing is curved on top, whence it runs down into a slant of about 45 deg., and then projects to form a receiving compartment at the front. The covers of the slanting and horizontal

parts are hinged together and to the front edge of the casing, forming a two-leaved lid which, when lifted and brought forward, opens the machine and at the same time forms a projecting work table. This hinged cover may also be brought to rest in two other positions, leaving the machine only partially open and the work table out of the way. The curved section of the casing is covered with a roll-top

Fig. 1.

shutter which serves as a covering slide over the exposure opening, permitting this to be varied in extent up to 150 deg. for rays from the sun, and up to 120 degrees or more for those from the electric lamps.

The printing is effected through a transparent covering-sheet which holds the tracing and sensitive paper down upon the surface of a felt-covered drum that revolves under the exposure opening concentric-

ally with the curved top of the casing. The transparent cover consists of a strip of the best tracing cloth over seventy feet in length, permanently fastened at one end to the drum and passing around this to a winding roll under proper tension. The tracing cloth is carefully prepared so as to wind true from roll to drum and back again, and its edge is spaced off into feet and marked with numbers which indicate the maximum length of print which may yet be made when part of the cover has been wound off. The cover-strip passes from the winding-roll up under an idler and then around this down to its contact with the drum, the material thus forming an inclined feed-

ments of any considerable drafting room or of a commercial blue-printing establishment, be regarded as of primary importance. The support is so wired as to be ready for connection to the mains of either a two- or three-wire system carrying 110 or 220 volts, direct current. The lighting arrangement consists of enclosed arc lamps, four, five or six of them for the three respective widths of the machine, or of a set of three or four Coper-Hewitt mercury lamps of the requisite length.

The most actinic rays of light from an arc lamp radiate in a beam outward and downward from the crater formed by the arc in the upper carbon, and the idea is to so reflect all the rays as to bring

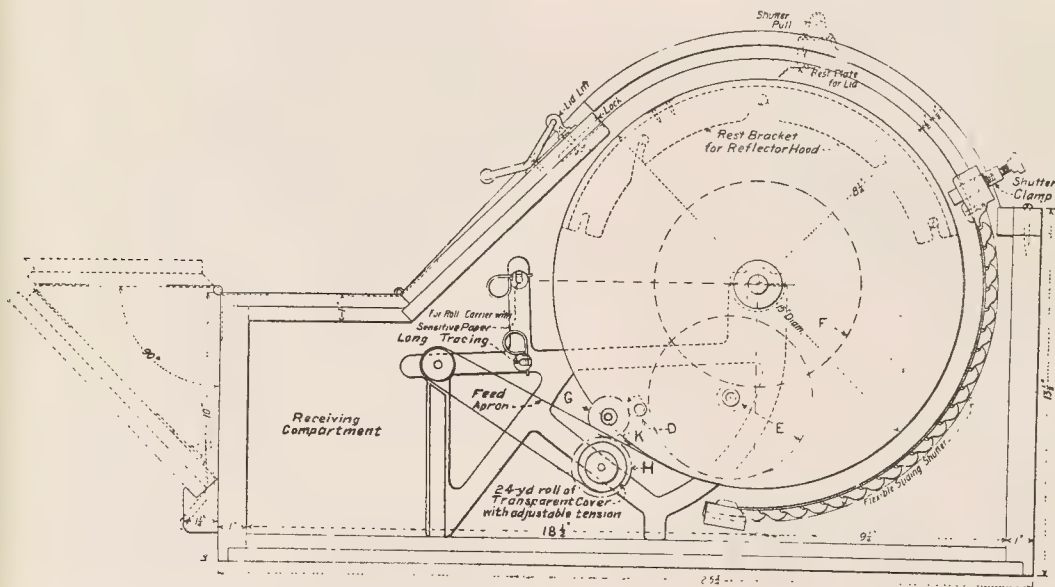

Fig. 2.

on down which the tracing and sensitive paper are carried into contact with the revolving drum, and thence around with it under the exposure opening. The printing is continued on the return of the drum, and after the printing the tracing and prints are carried up an inclined plane and delivered over the idler into the receiving compartment in front. The tension of the transparent cover can be varied by means of a friction brake at one end of the winding and can be effectively controlled so as to insure a close contact of sensitised paper with tracings on thick or rumpled tracing cloth at any desired printing speed.

The drum is actuated from the outside by means of a reducing gear-le from the motor to a driving spindle which passes into the drum and carries a small pinion on its inner end. This spindle is adjustable laterally so as to carry the pinion into mesh with either of two sets of reducing gears on the inside, one set serving to move the drum forward at a certain speed, and the other to move it backward at a faster speed. The spindle is held in either position by means of a spring catch which fits into either of two grooved collars carried by the spindle on the outside.

Three different speeds are provided, the return in such case being faster than the forward motion. The exposure goes on during the forward and backward movement of the drum. The combination of these various speeds affords a gradation of nine different speeds of exposure, and these may furthermore be varied by changing the lamp resistance attached to the motor. The use of cone pulleys or of an external rheostat for this purpose is thus advantageously avoided.

The machine, together with its electric-light supporting frame, is in three widths, affording prints up to thirty, forty-two and eighty inches wide respectively, all three being adapted to make numerous prints up to a length of seventy feet.

The electric-light support of this machine, though an extraneous part of the apparatus, must yet, in view of the practical require-

about a zone of uniform actinic force over the entire surface of the exposure opening of the machine. To this end the lamps are placed directly over the axis of the drum, under a reflector-hood (fig. 3) es-

Fig. 3.

pecially designed for the purpose upon the principle of reflection from the surface of an ellipse, as first demonstrated by the present inventor before the Franklin Institute at its meeting on December 21, 1904. The lamp and the enclosing reflector-hood are both hung from a sus-

pension beam adapted to be raised and lowered on a support over the machine, the lamps being held to the beam in a fixed position and the hood by chains that permit its being raised and lowered about the lamps. Through sight-holes placed for the purpose the hood can be adjusted over the lamps so that the arcs coincide with the focal line of the elliptical inner surface of the hood. In this position the rays that strike the inner surface are reflected towards the opposite focus of the ellipse. The suspension beam with its lamps and hood is then lowered until the ends of the reflector hood rest upon the brackets at the two ends of the machine casing. Thus placed, the reflected light is intercepted by the cylindrical surface of the drum, reaching it (and its overlying tracing and sensitised paper) in rays of equal length and in directions uniformly normal to the surface, thus producing the desired area of uniform illumination. For the long tubes of the mercury lamps, the same principle is applied in a form modified for the purpose. In either case the uniformity of illumination which is produced is such that tracings coming within the area of the opening can be effectively printed without moving the drum.

## Patent News.

*Process patents—applications and specifications—are treated in Photo-Mechanical Notes.*

The following application for patents were made between January 22 and 27:—

**DEVELOPING DISH.**—No. 1,883. A non-splash developing dish. Samuel Dawe and James Cook Thompson, 23, Elm Grove, Southsea.

**THREE-COLOUR SCREENS.**—No. 1,938. An improved process for producing three-colour screens for colour photography. Robert Krayn, 33, Cannon Street, London.

**PAPERS.**—No. 2,057. An improved process for making photographic papers. Ignaz Hoffsummer, 6, Lord Street, Liverpool.

**FILM CARTRIDGES.**—No. 2,136. Improvements in photographic film cartridges. Thomas Macwalter and Elliott and Sons, 322, High Holborn, London.

**CINEMATOGRAPH-PHOTOGRAPH.**—No. 2,157. Improvements relating to the synchronous operation of combined cinematographs and phonographs. Oskar Messter and Leon Gaumont, 7, Southampton Buildings, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**COLOUR PHOTOGRAPHY.**—No. 7,557, 1905. The claim is for the use of a number of dyes possessing a sharp difference in their powers of dyeing hardened and unhardened gelatine—that is to say, dyes which are taken up by unhardened, but not by hardened gelatine. Many dyes do not distinguish sufficiently in this way, but excellent results may be obtained if certain dyestuffs are used. For instance, the mikaado-dyestuffs obtained from paratrotoluenesulphonic acid, the soluble azo-dyestuffs, derived from dehydrothiotoluidine, primuline, or their homologues and substitution products, natural carmine, and sulphonic acids of induline and nigrosine, naphthazine blue and some of the diamine colours, like diamine pure blue, dianil blue, dianil yellow, dianil garnet (made from benzidine naphthylamine, disulphonic acid, and amidonaphthol sulphonic acid), and others. Of the anthraquinone dyestuffs may be used the aekylidoanthraquinone-sulphonic acids and their derivatives. For example, to produce a blue image, a gelatine layer sensitised by immersion in a 4 per cent. solution of bichromate may be exposed to light under a diapositive and excess of bichromate removed by washing with water. The layer may then be immersed in an aqueous solution of fast blue (indulinesulphonic acid) of say 4 per cent. strength, rinsed with water after fifteen minutes and then brought into intimate contact with a moist gelatine paper. After about ten minutes the paper may be removed from the layer, when it will be found to exhibit the image in blue. The original layer, without being re-dyed, may serve several times for reproducing the image or may be coloured again by immersion in a dyebath.

This process is of special importance in the manufacture of three-colour photographs. The operation may be conducted, for instance, as follows:—From the three negatives are made three diapositives under which are exposed the bichromate gelatine plates as described above. The gelatine plate, which corresponds with the red-screen negative, may be then dyed by immersion in a solution of about 4 per cent. strength of, for instance, diamine pure blue, and the image may be transferred to the gelatine paper as hereinbefore described. The gelatine plate, which corresponds with the green negative may be dyed by immersion in a solution of about 4 per cent. strength of carmine or of the azo-dyestuff from primulinesulphonic acid and 1: 4: 7-*a*-naphtholdisulphonic acid and afterwards washed. The previously obtained blue, still moist or re-moistened image may then be placed on the red plate in such a manner that the outlines cover each other, and closely pressed; after about ten-fifteen minutes the image is removed. The gelatine plate, which corresponds with the blue screen negative, may be dyed in a solution of about 4 per cent. strength of dianil yellow R (azo-dyestuff from primulinesulphonic acid and phenylmethylpyrazolone), excess of the dye-stuff removed by rinsing with water and the blue and red image laid on so that the outlines cover each other. After about fifteen minutes the finished image is removed from the plate. O. Imray, for Meister, Lucius, and Bruning, Hoescht-on-Main, Germany.

**PROTECTING PHOTOGRAPHS.**—No. 639, 1905. The claim is for a method of protecting finished photographs, consisting in applying a transparent film—which is supplied mounted in a carrier, as an article of commerce—the film being secured to the surface of the photograph by a coating of gelatine or shellac, which becomes adhesive by moisture or heat. The film is prepared by coating glass or other support with a solution of the transparent medium, such as celluloid, varnish, etc., and it may bear any design by which to ornament the photograph. Frederick Elijah Blaisdell, 15, Langland Gardens, London.

**PRINTING FRAME.**—No. 11,365, 1905. The invention consists of a printing frame, in which the negative is held by the rebated or chamfered edges of sliding pieces attached to the front of the frame. Negatives of various sizes can thus be accommodated.

in one frame. Walter Charles Grubb and Albert Nixon, Eagle Works, Durham Grove, Hackney, London, N.E.

**FOCAL-PLANE SHUTTER.**—No. 16,593, 1905. Details are given of the mechanism of a focal-plane shutter in which, among other movements, the slit is covered as the shutter is re-wound after exposure. The working of the shutter is as follows:—When the device is to be wound up and an exposure to take place, the handle 20 is turned and the winding-up rollers 3, 4 rotated thereby, so that the curtains 1, 2 are wound upon these rollers. During this movement the roller 3 moves the friction discs 8, which, in their turn, transmit their movement, through the rollers 11, to the winding-up rollers 4. The rotation of the winding-up rollers of both curtains continues until the pin 15 of the wheel 14 strikes against the projection 16. This stops the further rotation of the rollers 4. If now the handle 20 is turned further, the curtain 1 is moved further and displaced with relation to curtain 2 until the projection 21 strikes against the projection 22. According to the adjustment of the disc 24, the slit between the two blinds 1—2 will be more or less broad. If now the disengaging lever 32, by a pressure on the button 33, is moved out

of the teeth of the segment 31, the curtains are moved under the action of the spring stretching-rollers 5, 6. Both curtains are moved simultaneously, until the pin 15 of the wheel 14 strikes, from the other side against the pin 16, the same as during the winding-up. As soon as this takes place, the rollers 4 can no longer rotate. But the roller 5 can wind up the blind 1 still

further, as the coupling-rollers 11, when the friction discs 8 are turned in this direction, enter into a widened part of the inter-spaces 10 within the rollers 4 and thus uncouple the rollers 3, 4. During this movement of the curtain 1, independent of the curtain 2, the slit is closed, so that when the shutter is wound up again, no light falls upon the plate. Ernst Brauburger, Steglitz, Berlin and Optische Anstalt C. P. Goerz Akhengesellschaft, Berlin.

**STEREOSCOPY WITH ONE LENS.**—No. 21,909, 1905. The invention consists of two glass prisms placed as near as possible to the front of the lens and enclosed in a dull black casing. The two rectangular equilateral prisms 1 and 2 are so placed together that their hypotenuse-surfaces *a b* and *c d* are parallel. The length of the small sides *a c* or *b d* or *c b* is preferably 34 millimetres, that

Fig. 1.

is to say, a little more than half the distance between the eyes, for the purpose of obtaining the desired stereoscopic effect. The two prisms 1 and 2 are arranged in a casing 3, which is dull black inside and which is provided at the back with a socket 4 for the purpose of placing it on the lens of a camera. The front and the back surfaces of the attachment are uncovered for the purpose of admitting rays of light to the lens. In order to do away in this combination of prisms with chromatic phenomena due to the rays striking hypotenuse surfaces *a b* and *c d* at a smaller angle than 42 degrees (Figure 1), and to bring the image produced exactly into the centre of the sensitive plate of the photographic camera, the combination of prisms is arranged slightly outside the centre of *x y* of the socket 4 of the prism casing 3, and at an angle *α* to the object glass lens (Figure 1). The size of the shifting and of the angle of the combination of prisms relatively to the object glass, depends on the kind of glass

used. In the diagrammatic horizontal section (shown in Figure 3) through the camera with the stereo-attachment mounted in the centre of the lens, no attention has been paid to the shifting and to the angle of the prism combination required on account of the chromatic phenomena. If no attention is paid to the lines in that figure representing the camera, then the thick full lines

Fig. 2.

show the prism combination in one position and the thick dotted lines in the other position. The thin full lines and the thin dotted lines indicate the path of rays in the two positions of the stereo-attachment. By following the path of the rays, it will be seen that the hypotenuse surfaces *a b* and *c d* of the prisms, act as full reflectors, and further that the two surfaces in Figure 3 represented by the lines *a c* and *e f*, correspond to two lenses of the well known stereoscopic camera. The images produced,

Fig. 3.

formed by the reflection, fall, however, on the same spot of the sensitive plate, and not, as in the well known stereoscopic camera, on two arranged side by side. When using the stereo attachment, the camera is first sharply focussed. Any plate, film, and instantaneous camera of any size can be used, as long as it can be secured to a stand. The stereo-attachment is secured by its socket 4 to the lens, so that the projecting part *a* points, say, to the left hand side, see Figure 3 full lines, and then a photograph is taken. Then the sensitive plate is changed and the attachment is turned through an angle of 180 degrees, in such manner that it projects to the right, Figure 3 dotted. Then the second photograph is taken. Wilhelm Salow, 31', Neue Nordstrasse, Elberfeld, Germany.

**COLOUR PHOTOGRAPHY.**—No. 9,449, 1905. The present invention which is an improvement on that of Patent No. 1,008, 1904, consists in an optical apparatus of an optical system common for all three images, consisting of a double system of lenses separated by a highly dispersive analysing set of prisms, and provided with a shutter in front focal plane of the lens, or in the plane conjugate to the system, for the purpose of parallelising the elementary light pencils. The other part of the apparatus consists of three identical separate optical systems, each of which consists of a lens, a set of highly dispersive synthesising prisms, and, if desired, of another lens, for the purpose of enlarging or reducing the image, each set of synthesising prisms having a symmetrical position to the analysing prisms, while the intermediate lenses form a telescopic system. This in Figure 1 *a b* is common to all three pictures and the central part of it forms the analysing prism device, one of three lens-systems which

may be referred to as *c* (Figure 1) which direct the ray-pencils through rearward synthesising prisms; in some cases a further lens system *d* (Figure 1) is also provided, which serves for enlarging the image. For each picture four intermediate sets of prisms A, B, C, D, (Figure 1) are provided, the relative positions of which, with regard to each other, are such that the homogeneous rays due to the dispersal of each of the composite axial rays  $R, R', R''$  by the first prism A are parallel after passing through the second prism B; after passing through the third prism C the rays coincide in a point, and after passing through the fourth prism D they travel on together. A prism-system of this kind has the advantage that it may be optically corrected independently from the lenses used in the apparatus, since the pencils of rays passing through the prisms are subject to aberrational effects which neutralise each other. On the other hand the complication of the system, and the consequent absorption of light, are disadvantages. The method for simplifying the system,

Fig. 1.

to which the present invention relates, is based on the fact that by a special arrangement of the central lens-system *b* and *c*, the number of prisms in each branch of the system can be reduced from two to four, the optical correction of the whole being nevertheless preserved. The apparatus is provided in front of the lens *a* with a focal plane shutter *s* which renders parallel the main rays of  $R, R', R''$  and so on before they enter the prism A. Let the central lens-system *b, c* (Figure 2) be a telescopic, achromatic system of two lenses having a common inner focal plane. As is known, all rays which intersect each other in one point in the external focal plane of the first lens *b* are converted into pencils of parallel rays in the space between the two lenses, and after passing through the second lens the rays again intersect each other, in one point of the external focal plane of the second lens *c*. If, with a given prism, the point of intersection is determined for the outermost spectrum-rays, belonging to a given image and

Fig. 2.

due to the analysis of the multicoloured main-ray—i.e., *R*, and also the points of divergence of the spectral pencils corresponding to other main rays  $R', R''$ , and so on, these points will be found to lie in a certain plane peculiar to the prism tested. If this plane belonging to the first prism A (Figure 2) coincides with the focal plane of the second lens (*b*) and if the last or fourth prism D is given a similar position with regard to the third lens (*c*), both these lenses will have, as regards optical correction, exactly the same effect as the second and third prisms B, C. Figure 1, and the latter can therefore be dispensed with. In case the focal distances of both lenses composing the telescopic system are equal, the coincidence of above-mentioned planes is not necessary; it suffices if the distance of the said planes of divergence of prisms is equal to the distance of the exterior focal planes of the lenses *b, c*. Wernicke rectilinear prisms can be used, or prisms with deflected central rays. For the purpose indicated the separate parts

of the system must have fixed relative positions. The synthesising prism-sets cannot, therefore, be displaced for the purpose of dividing the beam into three beams of equal actinic power corresponding to the different degree of intensity of the plates, and it is in this case necessary to use auxiliary devices, such as can also be employed in apparatus comprising four prisms. These devices may consist of small mirrors or prisms producing total reflection, or the purpose of branching off the beams in three directions in the optical system can also be effected by deflecting the rays by means of small refractive prisms *p, p* (Figure 3). Since these small prisms have very small indices of refraction, the aberration due to their use is negligible. For producing larger deflections it is, however, desirable to make these small prisms achromatic, or to neutralise the effect of each small prism by an opposite effect due to small prisms introduced into the rearward branches of the system; for the same purpose the refractive index of the fourth prisms  $D^1, D^2$  can be increased. With the aid of these devices and by repeatedly deflecting the optical axis of each system, the pictures can be given any desired positions as regards the distances by which they are separated from each other, and they can also be brought into one plane for the purpose of being focussed on a single panchromatic plate. This latter position is

Fig. 3.

particularly useful when the purpose of the apparatus is reversed, that is to say, when instead of making three complementary negatives of an object, a projected image in natural colours is obtained, by synthesis, from three complementary colourless positives. The fixing of all three pictures on a single panchromatic plate facilitates in this case the obtaining of uniformity in the exposure to a powerful source of light required for the projection, and obviates the inconvenient centering of the separate pictures. This is more particularly important for the projection of a series of successive pictures, for instance, when the apparatus is used in combination with a cinematograph. Charles Julius Drac, Marienzstadt 21/23, Warsaw, Russia.

**EXPOSURE METERS.**—No. 19,962, 1905. The invention is an improvement of meters of the type specified in Letters Patent, No. 17,642, 1892. Four scale-marked discs are employed, giving readings for plate speeds, light values, diaphragm apertures, weather and subject. The meter may be constructed so that it is more compact, and may be supplied with projecting studs to facilitate the rotation of the movable scales. Ilford, Limited, Britannia Works, Ilford, and Rowland Samuel Potter, 97, Belgrave Road, Ilford.

MISS BEATRICE TONNESON, the Chicago photographer who has specialised in advertisement photography, is out with a new conceit. The idea is to surround a central picture with a cordon of smaller ones, in various poses and diversified costumes, "From décolleté to high stock gowns and garments, grave or gay; or, on gently pathetic expressions, set off those of a different kind," success or failure depending on the subject, the clothes worn in the various enveloping pictures and the care taken to see that they combine well together. It is even hinted that very interesting effects may be produced by margining the central photograph with former pictures of the present subject, who, if she be up-to-date in attire and the spirit of the time, represents merely perfection, not age; her former pictures besides being interesting reminders witness the gradation from the simpering maiden to the serene, self-possessed woman.—"The Photographer" (New York).

THE annual meeting of the Yorkshire Photographic Union will be held at Batley on April 7. The eighth annual excursion will take place on June 23, 1906, to York.

## Exhibitions.

### PHOTOGRAPHS BY ALVIN LANGDON COBURN, AT THE R.P.S.

As we announced last week, the house exhibition of the work of Alvin Langdon Coburn opened at the premises of the Royal Photographic Society, in Russell Square, on Tuesday last. The exhibition will be open daily from 11 to 5 (Saturdays inclusive) until March 31 in presentation of card. The walls hold 120 photographs, nearly all mounted in passe-par-touts, and therefore a little monotonous for this season. Of these 120 forty-four are portraits, and it is this portion of the exhibition which will be most worthy of study by our readers. We hold no brief for the latest thing in portraiture; neither do we for the oldest. We are quite prepared to be told that by those who have been in photography for years that many of Mr. Coburn's portraits are technical blunders, crimes in lighting, and demonstrations of ineptitude in the making of a print. We would ask studio critics such as these to assume—as we believe they may assume—that Mr. Coburn gets the effects he exhibits—on purpose. They may transgress the unwritten laws which photographers have striven to obey in portraiture since the profession of portrait photographer has existed, but there they are, and the fact remains that people well qualified to judge of them as portraits applaud them in no half measures. We suppose our professional readers do not care one brass farthing about the opinion their customers may entertain of them as technicians in photography so long as they esteem them as portraitists. And this is why professional photographers should visit the exhibition. It is one of the first opportunities they have had of seeing the work of one who discards conventions to portray the man who photographs to please himself, and, in spite of mannerisms, astonishes his sitters with the freshness and perceptions of his photographic portraits. Take two portraits which hang together—those of Mr. Fredk. Evans and Mr. George Davison. The former is alive with the bubbling volatility of the secretary of the Linked Ring. There you have Evans to the life, and one wonders whether such a long exposure of thirty seconds, which Mr. Coburn is in the habit of giving even to his sitters in sunlight—his lens aperture must be guessed at—is made without destroying the “go” of the portrait. It might have been given in the case of the equally characteristic portrait of Mr. Davison, who appears just as much at ease before the camera though Coburn were merely Swinfen-Eady. We like best the portraits in which a strong lighting has been used, and in the landscapes as well Mr. Coburn, it seems to us, excels in the handling of extremes of light and shade. But he will not avoid abnormal lighting merely because they are usually credited with being useful, and his catholicism in this respect sometimes leaves him with effects such as No. 4, a portrait of Robert Barr, which are unpleasant. Part of the secret of the success of many of the portraits is the fine sense of proportion shown by the photographer in placing his portrait in the space of the printing paper. We notice a number of instances where the height of the sitter is conveyed in this way, and the same skill can be seen in the landscapes.

The visitor whose lot it is to earn a living with his camera will be filled with the big question:—“Can photography of this kind be made profitable?” If prices are anything to do with it, Mr. Coburn sets a bright example to those in the rank and file of photography who lower the standard for all of us by cheapening the photograph in public estimation. The price of single copies (10 x 8) of many of the portraits in the exhibition is £5 5s. each, and though we have no idea what Mr. Coburn's charges are for sittings in the regular way of business, we have no reason to think that they are anything like as low as the high prices of a first-rate studio. If the man show at the Royal does this one thing, therefore—if it demonstrates that the production of an individual photograph at a round sum is a feasible proposition commercially—it behoves professional photographers to consider whether such a movement does not open up a new description of business; a business which at present appeals to the cultured few, but which assuredly will grow just as fast as taste in photographic production has been shown by the public in recent years.

Of Mr. Coburn's landscapes we are compelled to speak in a few

words. One characteristic of nearly all of them is the natural bigness he contrives to impart to representations of objects and scenes which are dwarfed by their surroundings. Show Coburn your back garden, with the request to give you a photograph of it (with water butt) of pictorial quality, and he would do it as Mr. Bernard Shaw says, “without effort,” or if you had no garden the water-butt alone would probably provide him with a “motif.” What a man to have about a studio, when photographing persons such as the individual who, at Penge, not long ago thrice confused the police by impersonating a small dust-bin! That is what impresses one in his landscape work, the way he singles out the most varied bits of a scene, and rescues them from pictorial oblivion in their surroundings. His eye for the picturesque is keen and discriminating. Nature as a whole, he seems to think, is all right, but let me select for you one or two delicate morsels from the profusion of good things. As a result we have some quite novel renderings of scenes familiar to all of us, so familiar, in fact, that we have never seen precisely the aspect of it which has given Coburn his picture, or, perhaps, having once caught a suggestion of it, have not had the patience to wait and expose and re-expose until the effect was secured.

## New Apparatus, &c.

The “Renaud” Quick Bromide Printer. Sold by Marion and Co., 25, Soho Square, London, W.

Designs of apparatus for the rapid production of bromide and gaslight prints and postcards have evidently occupied inventors' minds of late, a diversion of inventive genius for which the startling figures representing the sales of picture postcards is no doubt responsible. The modes of construction of these new pieces of apparatus are as different as the results they are called upon to turn out. The one before us, which Messrs. Marion call the “Renaud,” is singularly innocent of anything in the nature of movements or

machinery. It is assumed to be one person's work to look after an apparatus of this kind, and that therefore the printing of the negative may just as well involve the intervention of some primitive type of human intelligence such as may be assumed to be the possession of a hired boy or girl. Things are adjusted at the start by some one of experience, and the cards can then be taken off very rapidly from the negative by anyone who is able (1) to lay a piece of paper in a frame, and (2) count five. The apparatus consists of the box seen in the drawing and containing an electric lamp. Above the latter is a ground glass screen (D shown dotted in the figure), and on the top of the box a ground glass bed on which a negative up to

whole plate in size can be clamped. The clamping boards, B B, are adjustable for  $\frac{1}{2}$  plate, cabinet and postcard sizes, and prints from papers of these dimensions can thus be made from any negative between whole plate and the smallest sizes. Masks can be placed in the negative and vignettes or the ground glass shelf below. These and all other preliminary operations are performed with the light on, the switch E maintaining contact for this purpose. When ready for exposure, this switch is turned off, and the only way then of switching on the lamp inside the box is by bringing down the pressure board, F, on the card or paper which is laid on the negative. This movement at the same time cuts off the safelight G, and on pressure being released from the board after sufficient exposure has been given, the board rises, cutting off the light inside and re-establishing that outside. Hence the operator's hands are free to replace a new card for the exposed and to proceed in this way without any loss of time. The apparatus, as we have said, is simple in the extreme, and is sold at the price of 25s. complete with three masks, pressure boards in 5 sizes and wiring, and adapter to fit any household fitting.

The Quick Focus Kodak. Made by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

Quite a novel feature in hand-cameras is embodied in a new instrument brought out by the Kodak Company under the above descriptive title. The camera is a Kodak of the box pattern, and the novel movement lies in the focussing arrangement. A notched scale is provided on the side of the camera, and by means of it the instrument is made ready for focussing on an object at any distance between 6 and 100 feet. The lens, however, is not moved into the selected position until a button just below the scale is pressed, when the front of the camera flies forward and is held in the position. The exposure made, the front is pushed back flush with the camera

body and is so carried with all its working parts enclosed until a second subject presents itself, when it is again drawn forward to the same extension or to any other which at any moment before exposure may have been selected. There is an indescribable snap and smartness about the movement which should enhance its selling powers quite apart from the actual assistance which the device affords in accurately setting the camera to scale. The way in which the movement is worked out recommends itself to the purchaser, and the dealer's task in demonstrating the points of the camera is assuredly a light one. The Quick-Focus Kodak takes a  $5\frac{1}{2}$  by  $3\frac{1}{2}$  (postcard) picture, and possesses all the usual accessories in the way of finders, stops, time and instantaneous shutters. The price of the camera is 50s.

The "Togo" Printing Frame. Made by the Birmingham Photographic Company, Criterion Works, Stechford.

It is something to the credit of the Criterion Works that they have been able to design a printing frame distinctly different from the numerous patterns on the market. The "Togo" is as slim as its name implies—24 of it make a pile 6 inches high—and its construction is such that in mahogany it costs 6d., or it can be obtained in "leather board" for 3d. This is quarter plate size; it is made as well in the standard sizes, including, of course, the inevitable postcard. It consists of a frame in a rebated aperture in which the negative lies, and a double-hinged back which is clamped to the frame by a travelling brass spring. It affords a full view of the print.

An incandescent oil-light, said to be 400 candle power, is being placed on the market by Messrs. Van Wart, Son and Co., 106 and 108, Queen Victoria Street, London, E.C. It is known as the "Blanchard," and though advanced as a portable light for the use of builders and in workshops has obvious qualifications for purposes of photographic printing, etc. It burns paraffin at an estimated cost of one farthing per hour.

The Zeiss "Universal Palms" Camera.—In reviewing this camera last week we should have mentioned that although the body of the camera is built for 9 x 12 cm. plates, the dark-slides, film-pack adapters, and other exposure apparatus are made in quarter-plate size, and hence the instrument is immediately at the disposal of British workers.

Two patterns of Reflex cameras have been issued by Messrs. Houghtons, Ltd., as the "Holborn" Reflex, Nos. 1 and 2. The cameras are of the magazine type, carrying 12 plates in sheaths, and are made only in quarter-plate size.

RECEIVED.—The Wellington Light-Filter. (Wellington and Ward, Elstree, Herts.) To be reviewed in a later issue.

### CATALOGUES AND TRADE NOTICES.

A book-post card from H. and W. Green, Rotherham, reaches us as a reminder of the mount specialties of this active firm.

An immensely interesting book reaches us from Valentine and Sons, Ltd., Dundee. It is a collection of plate illustrations of the firm's various works, and gives a most striking and graphic account of the large dimensions to which the photographic and "process" publishing business has grown. Messrs. Valentine, we learn, turn out between one and two tons of picture postcards daily, and are producers of the postcard in every particular saving the cardboard and the ink. A new department of theirs is set apart to produce 1,000 coloured postcards of a view within a month of order. The book, which is a most vivid sidelight on the business doing and to be done in postcards, can be had for the asking.

A FIRM of enlargers and artists, exclusively for the profession, which has recently extended its circle of operations, is that of C. Corn, whose show rooms and London house are now open at 9, High Street, Islington. Enlargements in bromide, carbon, and platinotype, with finishing in oils and water colours, are the stock lines in which we have seen some extremely good work; but as that fact alone cannot be taken as any kind of testimony to a firm's services, we may be allowed to record our unqualified satisfaction with a purely personal piece of work—a water-colour enlargement—done for us by Mr. Corn, with a regard for the subject and to a degree of perfection which speaks volumes for the ability of his staff. A large variety of enlargements, with and without artist's finishing, is before us as we write, and if we refer to it at all it must be in terms of the sincerest commendation. Mr. Corn charges a fair price, one which obviously permits him to retain a skilled staff, and he maintains a standard of quality which must be for the good of those who entrust their work to him.

### New Materials.

A VERY attractive variety of title on mounts has been recently shown to us by Messrs. E. Osborne, 26, Red Lion Square, W.C. The name and address of the photographer is produced in embossed lettering on a tiny panel, surrounded by a line the same colour as the ground of the panel. The whole of the work of this two-colour embossing is done by Messrs. Osborne, and the effect is altogether a noteworthy distinction to a photographer's mounts. A sample mount from Messrs. Osborne's is the best means of appreciating the novelty.

SUNDERLAND Photographic Association.—The entries for the forthcoming exhibition should shortly be with the executive. Intending competitors who have not already secured entry forms (which include a facsimile of the handsome plaques which are being offered), should apply to the hon sec., W. E. Kieffer, Stirling Street, Sunderland.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
9.....	Photographic Society of Ireland	"The Use of a Camera on a Holiday." Mr. J. Stittard.
9.....	Bromley Camera Club	Lantern Evening. Affiliation Prize Slides, lent by R.P.S.
9.....	Aberdeen Amat. Photo. Assn.	"Velox, and its New Applications." Mr. W. Sadler.
9.....	Colne Camera Club	Yorkshire Photographic Union Members' Slides.
9.....	Loughton Photographic Society	"Mounting, &c." The President.
9.....	Sutton Photographic Club	"Exposure and Development." Mr. A. P. Hoole.
9.....	Leicester Lit. and Philo. Society	"Micro-Photography." Illustrated. Mr. J. W. Watts.
10.....	Aberdeen Photo Art Club	"The Principles of Artistic Selection." Mr. J. A. H. Hector.
12.....	Leek and District Photo. Soc.	"Carbon." Demonstrated. Mr. Howarth.
12.....	Oxford Camera Club	Exhibition of Members' Slides.

3.....	Chelsea and District Photo. Soc.	Annual General Meeting.

**LEEDS PHOTOGRAPHIC SOCIETY.**—On January 30, Mr. J. Page Croft demonstrated the gum-bichromate process. Although Mr. Croft gave a few hints on the preparation of home-made paper, the interest centred around the specimens of his machine-coated material, several pieces of which he developed during the demonstration. The paper is insensitive and must be sensitised by the user in a solution of bichromate. An ordinary gum-coating treated in this way would dissolve and run, but the "Page Croft" gum is hardened by the addition of methylated spirit and a small quantity of sulphuric acid. As a consequence, development can only be done with warm water containing a small quantity of caustic soda to assist it. A number of prints were successfully developed; several over-exposed ones required the solution boiling-hot before the image would appear, but in every case a normal print resulted. There was no sign of blistering, granularity, or other technical defects, their absence confirming the enormous latitude of the paper and the stability of the coating. The half-tone rendering was remarkably good.

**WHITEY CAMERA CLUB.**—Mr. W. Sadler, demonstrating Velox on January 30, said the point of the greatest importance was to choose the grade of paper most suited to the negative. When in Scotland, the demonstrator found that Dr. Richmond claimed to be the inventor of what was known as the Blake-Smith process, so he called it the Dr. Richmond Blake-Smith bath until the question of the originator was settled.

**CHELSEA PHOTOGRAPHIC SOCIETY.**—In the course of a demonstration on February 1, on enlarged negative making, Mr. A. S. Long explained that the process was very similar to bromide enlarging, but it would be remembered that the plates used were very much more sensitive to light than bromide paper. The yellow cap on the lens was quite inadmissible, and focussing should be done on a ground glass screen or on white paper packed out to the thickness of the plate used. Care should be taken that there was an even lighting over the whole surface of the subject being enlarged, and a slow backed plate should be used.

**ROTHERHAM PHOTOGRAPHIC SOCIETY.**—On Tuesday, January 30, the Rotherham Photographic Society entered into the occupation of new premises in Frederick Street, formerly used as a social club. These permanent quarters adjoin the premises of Mr. J. Leadbeater, and in becoming the tenants the society has expended some £40 in necessary alterations. This sum has been subscribed by the members, and has been devoted to the erection of an outside staircase, the decoration of the room, the re-arrangement of the lighting, including the installation of the electric light (for the use of the lantern), and the provision of a dark room where members can change and develop their plates. It is confidently anticipated that the acquisition of the new room will result in an addition to the membership of the Society, as by its means amateur photographers are now provided with facilities such as they have not had before in Rotherham. This forward step has been taken by the society at the conclusion of sixteen years of existence, during which time, it is satisfactory to record, the society has been entirely self-supporting, and has never appealed for funds outside its own ranks. The society owes much to its president, Mr. J. Leadbeater, and its secretary, Mr. H. C. Hemmingway, by whom at the opening of the new premises, a statement was made as to the council's plans for the society's future prosperity. He believed it was the intention to arrange for more frequent meetings, at any rate bi-monthly meetings; and if some of them partook more of friendly talks on matters photographic than set papers, it might be advantageous. At any rate, it was thought they might devote a little more attention to the more elementary part of the art-science; and he was quite sure that some of the older hands who were experienced in photographic matters would not hesitate two minutes to tender what help they could to those who were in the early stages. Those present had seen what the society had to offer. The dark room was intended to be opened on certain fixed hours on every weekday, and the meeting room also would, of course, be open for photographic purposes. The enlarging lantern would also be available.

We congratulate Rotherham and the society on this satisfactory state of affairs.

**WALKLEY CONSERVATIVE CLUB CAMERA SOCIETY (SHEFFIELD).**—The hon. secretary, on February 1, gave a demonstration of the new Page-Croft pigment paper. A number of prints were developed, showing the ease and simplicity of the process. The lecturer recom-

mended users who sensitised their own paper to take the paper out of the sensitising bath immediately the paper became limp. Much brighter prints had been the result, in the lecturer's hands, through doing this. The paper would yield any amount of detail, sufficient almost to satisfy the amateur who worked glossy P.O.P., whilst it was a *sine quâ non* for the impressionist and artistic worker. Any amount of hand work could be put in, the best way to do this being the one recommended by the maker of the paper, "after development has been carried as far as thought fit, the print should be dried (in the dark), then pinned on a board, dampened, then one could work on it to his heart's content." The lecturer found the paper at least six times as fast as P.O.P.

**SOUTHAMPTON CAMERA CLUB.**—At the meeting held on February 5 the winner of the lantern-slide competition for landscapes proved to be Mr. H. Essex, whose work is rapidly attaining high merit. Mr. R. Robinson was second, and Mr. Essex and Mr. E. E. Rye tied for third place.

**PLYMOUTH PHOTOGRAPHIC SOCIETY.**—At the meeting on Friday, February 2, Mr. J. T. Johnson, president, in the chair, Mr. W. Chas. Johns gave a very excellent paper on "Lantern Slide-Making by Artificial Light." He showed that in slide-making it was necessary to have a theoretically perfect negative, one full of detail, without great contrasts, and with delicate gradation everywhere. Having obtained the right negative the method adopted consisted in using Wynne's printing meter to obtain the test number, and this secured, correct exposure was obtained, if the same lantern plates and developer were used. It was advised that one plate and one developer should be always the practice. In connection with exposures, the list of lantern plate speeds compiled by Watkins, was considered desirable to use. A series of experiments which he had made enabled the lecturer to say exactly how much light should be used for varying negatives as tested under the Wynne print meter, and this, once settled, always remained good for the purpose. Magnesium wire was the source of illumination, and the length of the piece necessary for any given exposure had been worked out.

## News and Notes.

**BERMUDA ARROWROOT**, which is often recommended in preference to others for mounting purposes, is the subject of a letter to the "Chemist and Druggist" from W. T. James, of Bermuda, wherein it is pointed out that he is the sole maker of arrowroot shipped from Bermuda to England to his agents, Messrs. George Harker, 101 and 103, Upper Thames Street, E.C. He writes:—The purest arrowroot in the world is grown and manufactured in Bermuda: it is different in almost every respect from the arrowroot starches prepared in other countries. The purity of the Bermuda arrowroot which I manufacture is the result of the special care and attention which is exercised in every detail of the various processes of preparation from the root to the finished starch, all of which are carried on under my personal supervision. The water used in connection with the washings through which the pulp passes is an important factor in the purity of the starch. This water is rain, caught and stored in specially constructed stone tanks, and as there are no factories or other sources of atmospheric contamination in the Bermuda Islands, the result is a water of unquestionable purity, absolutely free from the foreign substances usually found in that procured from springs and rivers. The crop of arrowroot for 1905 was an exceedingly small one, and with the consequent limited supplies going to London it has undoubtedly given the opportunity to certain unscrupulous people to work this fraud upon the unsuspecting grocer or druggist, who in all innocence passes it on to the public. This year, however, the crop will be larger, and I trust to be able to ship a quantity sufficient to enable dealers to procure their supply of the genuine article.

**THE Northern Exhibition.**—This important exhibition, held annually alternately at Manchester, Liverpool, and Leeds, will this year be held at Manchester, and be open from April 27 to May 7 inclusive. It was hoped that the Manchester City Art Gallery would have been available for the exhibition in the same manner as the Art Galleries at Liverpool and Leeds, but after negotiations lasting over eleven months the Art Gallery Committee found that

the space at their disposal would not permit of their allowing any of the rooms for the purpose of a photographic exhibition. This has caused the date of the exhibition to be delayed in announcement. The fine room at the Manchester Athenæum has been secured, and every endeavour will be made to ensure a first-class exhibition. The Rev. H. W. Dick has been appointed chairman of the executive and various committees formed for carrying out in an efficient manner the details. Much energy is being shown by the Manchester men, and we feel sure their results will be satisfactory. We may say there will be no local selection committees as at Leeds; all pictures will be selected by the judges only. The prospectus will be ready in a few days.

**FATAL Photographs.**—Advices from the Baltic provinces state that many of the Lettish revolutionaries have been captured owing to the fact that, during the early stages of the insurrection, armed national militias were formed in different places, the members of which indiscreetly displayed their enthusiasm for the cause by having themselves photographed in groups in uniform. These photographs subsequently fell into the hands of the authorities.

## Commercial & Legal Intelligence.

**CUTTING Copper.**—In the City of London Court, last week, before Judge Rentoul, K.C., a claim was made by Mr. Henry W. Puetz, 4, Savage Gardens, against the Farringdon Works and H. Pontifex and Sons, Limited, Shoe Lane, to recover £3 13s. 1d. under somewhat peculiar circumstances. The plaintiff had a large sheet of beautifully polished French copper which he wished to have cut into pieces for the purpose of photogravure, and he sent it to the defendants to cut. They charged him 1s., and now the plaintiff said that they had spoiled the copper sheets completely, and that they were valueless to him. The copper had been scratched and dented and cut badly.—Mr. Godley, defendants' counsel, said they took no responsibility in the matter, and they told the plaintiff's representative when he brought the copper. That was denied.—Mr. Osborn, plaintiff's solicitor, said the copper was only fit for scrap copper now. It had been dogs-eared.—Mr. Godley said the defendants were in the habit of cutting great masses of copper. Had they known the plaintiff's copper was for the purposes of a photogravure they would have declined to have anything to do with it.—Judge Rentoul inspected the copper on the bench, and said it seemed to him to be scandalously cut altogether. No firm ought to undertake such a job and spoil men's goods, even if it were done cheaply. The defendants fixed their own price. The copper was not now fit even for a fire screen.—Mr. Osborn said it was worth nothing to the plaintiff.—Mr. Godley said it must be worth something. It weighed 45 lbs., and copper was worth 1s. 2d. per lb.—Judge Rentoul said the defendants held themselves out as copper-smiths, and they could not free themselves from having to act with rational workmanlike skill, which had not been done in that case. He could not hold that the work was properly done, and he must find for the plaintiff for the amount claimed, with costs. Of course, the defendants could appeal if they liked.

**A PHOTOGRAPHIC Operator's Claim.**—In the City of London Court, on January 26, an action was brought by Mr. A. G. Field, 20, Bishopsgate Street Without, operating photographer, against Mr. Zelter, of the New British Art Studio, photographer, 84, High Holborn, to recover £1 13s., a week's wage, in lieu of notice.—Mr. Martin O'Connor, plaintiff's counsel, who appeared at the instance of the Photographic Society, said the case was one of some importance, affecting, as it did, the whole 15,000 members of that society. The plaintiff had been discharged without any notice, and the reason given by the defendants was that operating photographers were daily servants and could be sent away without any notice. The plaintiff's society was anxious to have the custom maintained by which operating photographers, people who touched up photographs, etc., were entitled to a week's wages in lieu of notice. The defendant now informed the Court that he would not contend that the plaintiff was not entitled to a week's wages unless he was wrongly dismissed. He discharged the plaintiff because he was insolvent, having snapped his fingers in his (defendant's) face, and said his business was a "dish rag." The

plaintiff said that was quite untrue. He had been dismissed on the ground that he was a daily servant and was not entitled to notice. There was an altercation between the defendant and himself, and the defendant spoke very sneeringly of the fact that he was an operator. The next night he was told to go, having been kept on for two days after the supposed insolence, which he denied.—Judge Rentoul, K.C., said if the defendant had dismissed the plaintiff for insolence immediately after it happened, there might have been something in his statement, but the plaintiff had been allowed to work for two days after behaving, as the defendant said, rudely. The defendant had waived the offence, if any had been committed, and he would not decide there had been any. Judgment for the plaintiff for the amount claimed, with costs on the higher scale, because the action was of importance to all photographic operators.

**INDECENT POSTCARDS.**—At Bow Street, last week, Ivan Paperno, a stationer and tobacconist, of City Road, Shoreditch, was summoned under the Vagrant Act for exposing indecent picture postcards in his shop window.—Mr. Muskett, who supported the summonses on behalf of the Commissioner of Police, said that in the course of the last few months there had been an undoubted recrudescence of the traffic in indecent pictorial postcards. Many prosecutions took place a year or two ago, and it was hoped that the sale of such postcards had been stopped; but the trade was now reviving, and cases were coming under the notice of the Commissioner of Police from all parts of the metropolis. Having regard to all the warnings which had been given by previous prosecutions of this kind, he ventured to suggest that it was time to consider whether an example should not be made in such a gross case as this was by committing the defendant to prison as a warning to others.—Sub-Divisional Inspector Coles gave evidence of the seizure of a large number of pictorial postcards at the defendant's shop, as to 846 of which he applied for an order for destruction.—Mr. Fenwick said that, with the exception of one or two of the cards, which were on the border line, they were obscene or indecent. He made an order for the destruction of the cards, and imposed the full penalty of £25 and 5s costs, with the alternative of two months' hard labour. He refused to allow the defendant time to find the money.

**BANKRUPTCY at Brentford.**—The official receiver for the Brentford district has issued particulars in the failure re Francis Crichton Temple, residing at "Cassillis," St. Margarets-on-Thames, from which it appears that the debtor has filed a statement of affairs showing gross liabilities amounting to £4,124 12s. 2d., of which £1,500 is expected to rank against the estate for dividend. The assets are estimated to produce £1,199 3s. 8d., from which £13 15s. has to be deducted for the claims of preferential creditors payable in full, leaving a nett assets at £1,175 7s. 10d., and disclosing a deficiency of £324 12s. 2d. The report and observations of the official receiver are to the following effect: The act of bankruptcy on which the receiving order was made was the failure of the debtor to comply before the 25th day of November, 1905, with the requirements of a bankruptcy notice duly served upon him. The petitioning creditor is Mr. C. A. Nussey, of 1, Great Winchester Street, E.C. The debtor, who has been adjudged bankrupt, states that from September, 1904, to the date of the receiving order, he was managing director of a limited company at a salary of £100 per annum, commencing from March, 1905. He has now no occupation. The debtor's affairs were liquidated by arrangement about the year 1880. The debtor states that nothing was paid under the liquidation, but that he has since paid all the creditors he could find in full. The unsecured liability is in respect of money lent. The debtor has omitted the petitioning creditor's claim, amounting, it is understood, to £3,600, from his statement of affairs. The creditors stated to be fully secured hold first and second mortgages for £1,500 and £800 on the freehold house, "Cassillis," where the debtor resides; first, second, third and fourth mortgages for £1,350, £500, £460 16s. 4d., and £700 on land at Egham and Staines, and a mortgage for £100 on land at Shepperton. The creditor stated to be partly secured holds a bill of sale on the debtor's furniture. The contingent liability is in respect of £800 partly paid-up shares in the company of which debtor was managing director. The debtor attributes his insolvency to "being compelled to compromise an action owing to insufficient funds to contest to the end a claim he disputed." He admits that he was aware that he had not sufficient property to pay his debts in full in May,

1905, and has furnished the following account:—Bad debts, £47; household expenses from 19th December, 1904, £252 12s. 2d.; interest on borrowed money, £100, making a total of £399 12s. 2d.

**A PHOTOGRAPHIC ELECTION CARD.**—Before Mr. Justice Darling, in the King's Bench Division last week, Mr. W. A. Bird was granted relief under the Corrupt and Illegal Practices Act, 1883, for an offence against section 18. It appeared that Mr. Bird, agent for Sir F. Dixon-Hartland, M.P. for the Uxbridge division of Middlesex, sent out picture postcards bearing photographs of the member and his wife. At the suggestion of the printer, the word "Vote" was put upon the card, which, without its being recognised at the time, constituted the card a bill within the meaning of the section, and rendered it necessary for it to have had an imprint of the printer and publisher. Omission of the name of the printer constituted the offence.

**THE SITTER'S RIGHTS IN FRANCE.**—A case of great interest to photographers and popular actresses came before the courts on January 30th. In 1902 Mme. Nadille de Buffon, the statuary artiste, was photographed in the costume of the Queen of Saba, the photographer executing his work at a reduced price—the "prix d'artiste," as the custom is called. In the following year Mme. de Buffon was greatly surprised to find that her photograph figured on postcards, with her name at the foot. She complained to the photographer, who replied that as she had paid an artiste's price she had been treated as an artiste, and that in virtue of this reduced price he had the right of reproduction. Nevertheless, he added that he would give the necessary orders for the sale of postcards bearing the photograph in question to cease. At the end of several months, however, Mme. de Buffon saw that the photograph was still on sale, and she took action against the photographer. The Court found that the photographer could not make use of the photograph without the authorisation of the person concerned. Mme. de Buffon, the judgment ran, went to the photographers of her own accord, and though she had been favoured with special terms, she had not given her permission for her likeness as Queen of Saba to be reproduced. As to the declaration of the photographer that the "prix d'artiste" implied the right to reproduce, that was only a question of custom, and not of law. The Court granted an injunction against the sale of the photograph, and ordered the photographer to pay Mme. de Buffon 500 francs damages.

## Correspondence.

### PHOTOGRAPHING THE EYE.

To the Editors.

Gentlemen,—Can you suggest a method of taking life-sized or enlarged photographs of the human eye, so as to give all the finer delineations of the iris? I find the ordinary direct method almost useless on account of the difficulty of obtaining definition, and the long exposure. The recent discovery that every portion of the body has its representative portion in the iris of the eye, makes it highly necessary to obtain reliable photographs thereof, and the discoverer (H. E. Gane, M.D.), says that photography fails to record the finer markings.—Yours faithfully,

ARTHUR WHITING.

February 1, 1906.

[We believe the best photographs of the eye have been taken by flashlight in a way such as that of Dr. Walter Thorner described in our issue of February 3 last year.—Eds., B.J.P.]

### COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—Presumably on the old legal axiom "qui fecit per alium fecit per se," Dr. Grün saddles you with my criticism of the exhibition of colour photographs. Whilst this may be good law,

it is not always justice. I therefore claim permission to reply to one or two points in your correspondent's kindly letter.

I fully recognised that many of the Brighton results must be only considered as experiments, and the conclusion I came to and expressed was that they were not satisfactory as modifications of known processes which do give good results. I am glad to see that Dr. Grün has come to the conclusion that "the results must be on one surface," but if by his next definition he wishes to infer that three superimposed films cannot give perfect results, then I differ entirely from him, as must everyone who examines the late-hung portrait by the Rotary Photographic Company's superimposed carbon tissues. I have had the opportunity of examining this at leisure more than once, and I certainly should now place this far above any other exhibit in the room—as a portrait from life. On further consideration of No. 11 by the Sanger Shepherd imbibition process, I begin to have qualms as to whether this is not a copy of a water colour or pastel drawing.

If Dr. Grün uses the term "films" as confined to a colour print on a celluloid base, then I am quite in accord with him.

I had not the slightest intention of being unduly hard on any exhibitor by pointing out specific faults such as want of superposition, except that I accepted the exhibits as the best which could be made by the process of which the exhibitor was for the moment the authority. With this in view, any defect such as this can, I think, be legitimately laid stress on, because it may or may not be the fault of the process. If it is the former, then it is the duty of a technical critic, and it was solely as such I wrote what I did, to point this out; if, on the other hand, it is not the fault of the process, but purely an accidental failure, then I am bold enough to say that the result should not have been shown or an explanatory note appended.

With regard to Dr. Grün's remarks re paintings not being "exposed to criticism as to brush marks or peculiarities of pigment," I would say that this is entirely a matter of personal opinion, and I think I can prove my statement by relating a little experience which befell me some years ago. I was in extremely friendly relations with an artist, who one day complained most bitterly of some photographs of his pictures. Even then, and it is now fourteen years ago, I knew a little about colour and its reproduction, and offered to make a satisfactory result of one picture. On submitting the print to him he said, "Yes, the colours are better rendered—they're nearly right—but, man, you've wiped out the brush marks—the technique—of the thing," and this after I'd spoilt four or five plates in getting an even surface, for I always believed this man squeezed his tubes on the canvas and then worked the paint as squeegee as possible, so that he left not ridges but mountains of pigment.

The next point is, Are we to reproduce nature as we see it in colours, or as it is? If, as Dr. Grün says, different observers see the same subject in nature differently, then I contend if we can give an absolutely faithful reproduction in colours of nature as it is, the same observers will also see the reproduction differently, and we shall have obtained our aim.

Now, I am not aware whether you, gentlemen, possess one or several black kittens or any kittens at all; but the black kitten referred to belongs to me, or at least to my little daughter, and as I belong to her I presume that the kitten belongs to me. Now this kitten is black, there is no question about that, it is the one point on which he prides himself and on which his little and big owners pride themselves. It may be egotistical, but I really do pride myself on the fact that this is the blackest kitten I ever did see. He is in no way brick-red, and Dr. Grün's assumption that he had a red reflection is erroneous; why, he does not even wear a collar. But I would like to point out that Dr. Grün's statement as to the negro's face is entirely beside the mark, for he should know that a negro's face is to some extent a reflective surface, secondly it is not black, and thirdly the surface of a cat is entirely different to a skin. In the former case we are looking on a smooth, more or less transparent surface, with a dark coloured pigment; whereas in the case of fur we are looking more or less on the ends of transparent tubes filled with a black fluid, in which by repeated reflection there is absolute absorption of light. A moment's consideration will at once reveal the fact that the man who first made black velvet merely copied a black cat's coat, and this is why black velvet is so black.

Dr. Grün's charge of unfairness cannot be upheld. I did not criticise the exhibits by what I thought they ought to be, but rather from what I know of nature, and I still maintain that the majority of the Brighton exhibits are false in colouring judged from actual knowledge of many of the places actually portrayed.

With regard to the letter from the Rev. Mr. Barker, my duty was to comment on the exhibits and not on what had been described in the press, but which did not materialize. Had I done the latter should have had to write a text book on colour photography, and we should all of us have been most abominably bored.—Yours faithfully,  
E. J. WALL.

Sidcup, February 3, 1906.

## PHOTOGRAPHING FURNITURE.

To the Editors.

Gentlemen,—I would like to supplement your paragraph in last week's "Ex Cathedra" re photographing furniture. For the last six years I have been employed professionally in this work. There is no doubt about its various difficulties pointed out by you, especially about the inlay (or banding) work which photographically is often the same colour as the woodwork; mahogany often being very red and the inlay a dark yellow and often very much stained with the polish. You speak of photographing it before the polish is applied. This is hardly practical, as you spoil the appearance totally, as the whole thing then looks dull, and quite unlike mahogany (more like cast iron). With reference to reflections the piece must be placed in such a position or the light so cut off as to have as little light play as possible. I never use a light-filter, but always an ortho' plate, unless, as in some cases, the contrast would be lost by so doing. A rapid plate and short exposure with long development will be found best in most cases. My reason for not using the screen is that time (commercially) won't permit of such prolonged exposures. I enclose a few specimens of mahogany inlay work so that you may pass judgment on this method.—Yours faithfully,  
F. G. WILLIATT.

157, Gordon Road, High Wycombe.

February 5, 1906.

[The inlay work is well rendered in some of the specimens sent by our correspondent, though we must own ourselves at variance with his method of short exposure and forced development. His negatives would benefit in gradation, we believe, by a fuller exposure and easier development, but the prints before us are nevertheless interesting as showing the amount of contrast obtainable without a filter.—Eds. B.J.P.]

## FLASHLIGHT PORTRAITURE.

To the Editors.

Gentlemen,—We enclose you herewith three photographs, examples of flashlight work. They are three of a series of nine taken by us on Saturday evening last at the final dress rehearsal of the "Hildenborough Village Players," whose first performance of last night (February 5) has been noticed by the principal London daily Press.

They were taken on Saturday night, and we used three Todd-Forrest lamps placed about 15ft. from the stage upon high step-ladders, two lamps on the right and one on the left. The camera was in the centre and about three or four feet behind the lamps, which we shaded from the lens by suspending pieces of old scenery from a cross-bar in the room. Lens used, a Dallmeyer Triple Achromatic, old pattern stop  $f/16$ . The exposures varied from one to two seconds, using about one drachm powder in each lamp, and Barnet "Red Seal" plates (not backed). You will understand the prints sent you, with the exception of the one marked No. 1, are quite rough, and have not been dodged, and are open to improvement by treatment.—We are, gentlemen, yours faithfully,  
ESSENHUGH CORKE AND CO.

39, London Road, Sevenoaks.

February 6, 1906.

[The three photographs are excellent examples of fully exposed groups, and the number of persons, from nine to sixteen, included demonstrates the illumination over a considerable area obtained by the means described by our correspondents.—Eds., B.J.P.]

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

L. Harris, Wesley House, Merthyr Tydfil. Two Photographs of D. A. Thomas, Esq., M.P. Photograph of J. Keir Hardie, M.P.

Thorncroft, 45, Wardlaw Avenue, Rutherglen, N.B. Three Photographs:—Baby Lying in a Fancy Cot. Little Girl Standing on a Stair. Little Boy Standing on a Seat with a Whip in his Hand.

Field, 38, Rowland Road, Leeds. Photograph of Sir J. L. Walton, K.C., M.P. amilton Toovey, 36, Royal Parade, Jersey. Photograph of Pottery, Flint, Tatchets, &c., Discovered in the Cromlech near Mount Orgueil Castle, Gorey, Jersey.

Argreaves, Fair View, Dalton-in-Furness. Photograph of Declaration of Poll at Ulverston on January 24, 1906.

R. Nichols, 30, St. Peter's Street, Stamford. Photograph of Opening of the Public Library, High Street, Stamford, by Earl Brownlow, January 25, 1906.

**DARK-ROOM LIGHT.**—Will you kindly inform me which is the safer light—red or yellow, for the above—specially, of course, for the chromatic or other fast plates? My dark room has two windows, with shutters to curtail light, or shut it out. One window has two plates of yellow glass, the other, one plate of dark red. At night I use a fairy paraffin lamp inside one of the large ruby lamp glasses, such as our womenfolk warm the drawing-room with, but outside this I put a sheet of yellow paper.—H. W. CASE.

We should advise you to get a ruby filter for rapid plates, and a yellow one for bromide papers. Better have these fitted to a good lamp and work entirely by artificial light. If you look among the notices of "New Apparatus" in the "Almanac," you will see several such.

**A.**—You will find the dextrine mountant given on page 984 of the "Almanac" perfectly satisfactory if you follow the directions closely.

**JOHNSON.**—We have forwarded your letter as suggested.

**NOTION.**—The studio as shown in the sketch is about the best you could build under the circumstances. In reply: (1) Yes. (2) Yes. If you had the studios raised more from the ground—say three or four feet—you would not be so much shaded by the wall. (3) We should suggest light green for the blinds.

**WRIGHT.**—(1). Yes, but a foot or two wider would be advantageous if many large groups have to be taken. (2). That shown in sketch "B," is very suitable. (3). All things considered, we should say that according to sketch "B." (4). Ground-glass, if kept clean, is very good for a south aspect. (5). Yes. Very well. (6). Yes. (7). We should recommend a dark green for the blinds.

(8). These would be very useful for both the sides and top, more especially if they were arranged so that they could be set at an angle if desired.

**WRIGHT.**—Will you kindly inform me if in making a series of postcards copyright it is necessary to register each one separately, or in the series, say six or more, be reproduced on one sheet so that one registration fee would cover the lot?—PYRO.

Each must be registered separately.

**JOHNSON.**—It is contrary to our custom to answer questions such as those you put to us.

**WRIGHT.**—Would you inform me if I am at liberty to copy a photograph? There is no name on the photograph or mount, and I don't know where to send for permission.—J. W. H.

You have no right to make a copy. If you do so you must take the risk of action, though it is not likely that any will be brought. Are you certain that the copyright is the photographer's? If he was paid for his work it is the property of the person who paid him.

**SHER.**—You were very unwise, in the first instance, in accepting

the prints at all. They should have been returned at once as being bad. As you have sold them, although at a reduced price, you will have, we suspect, some difficulty in recovering much of your money back, except that from the unexecuted part of the order.

**POSTCARDS.**—Will you kindly say what is considered about the average price paid by publishers of popular local views and picture postcards for whole-plate view negatives, selected from stock by them?—OPERATOR.

There is no average price. It is always a matter of arrangement between buyer and seller. Of course, views that can be repeated any day are not paid so much for as those taken under exceptional circumstances, and which cannot be again taken. You surely can better assess the value of your work, and the influence the publication of postcards from it may have on your future sales of it, than any one else can.

**SHARP PRACTICE.**—We shall esteem it a great favour if you would kindly give us your advice to the following:—We engaged a photographer in another town to take a certain quantity of negatives for us, and paid him so much per dozen. The actresses

would not have gone to him if it had not been for us. This photographer, instead of taking the quantity ordered, took double that. He sent us what we ordered, and he kept the others, without mentioning a word to either the sitters or to us. One of the sitters asked him when she could see a proof, and he answered that it had nothing to do with him, as the negatives were ordered and paid for by Messrs. ———, and she could only get proofs from them. A few days later, this photographer produced postcards of these actresses, in different positions than he sent us, and put them on sale in stationers' shops all over the town, without the consent of the sitters and us, before we had a chance of producing our own. The sitters strongly object to him selling their postcards, and it has greatly interfered with our business. What we want to know is: Can we claim damages for loss of business, and for producing postcards of these people, as we would have been the only firm to produce postcards of these actresses in these particular dresses?—GLASGOW.

It seems to us, according to the ruling in the Crooke-Irving case, reported in our issue of July 21 last, that the copyright in all the negatives taken belongs to you, and that you can restrain the publication of any copies from them. You can also recover damages for the injury done to you. We should advise you, without delay, to put the matter in the hands of a solicitor, and bring the ruling in the above case before him.

**COPYRIGHT.**—I should be pleased if you would answer the following:

I photographed a group; I copyrighted it; then gave a print to each person on group "as asked for." Sometime after one of the members of the group buys a copy in the ordinary way as a customer would. Could he then give permission to anyone to publish it without my permission?—A SUBSCRIBER (Norwich.)

If you were not paid for taking the group the copyright belongs to you, and to you solely. The mere fact that one of the party purchased a copy of the picture does not give him the right to publish it without your permission. If the picture is thus published you can proceed against the publishers for infringement of copyright.

**WATER FOR PHOTOGRAPHIC PURPOSES.**—Our premises are heated by a hot-water apparatus—iron pipes. When the water boils it is rusty in colour, but when not boiling is apparently quite clear. Is this water, when not boiling, suitable for use in washing prints, silver, i.e., to take the chill off tap water? Of course, the toning baths are not made up from this water; if injurious, how can the water be made suitable? Could this be done by the use of a filter, and what sort? I may say that I have a supply over the dark room sink and use the hot water frequently when not at boiling point in developing negatives, and find no ill results, and have also known the "demonstrators" from a leading firm use this hot water from the same supply, and not offer any objection to its use.—FERRI.

We should say that it is undesirable to use this water for any photographic purpose, unless it were filtered to ensure the removal of iron particles. If it is used, we should advise that the taps be covered with two or three thicknesses of close flannel,

tied loosely on so as to form a sort of bag to keep the particles of iron oxide back. This bag should be frequently renewed. In this way the water may be utilised.

**POSTCARDS.—ARTIFICIAL LIGHT.**—I should be greatly obliged if you could answer me the following:—1. How are postcards and midgets from wet negatives (while you wait) done? Is a plate the size of a midget used, or so many taken on a larger size plate? 2. Name and address of the makers of the Aristo arc lamp? 3. What illumination for enlarging is more powerful than incandescent gas? I have electric light installed. If that would be more suitable what form of lamp should be used?—O. B.

(1). Usually several are taken on the plate. The negative, after a good rinsing, has a piece of bromide paper squeezed upon it, with the interposition of a thin piece of clear celluloid, then exposed, and developed in the usual way. (2). Kodak, Ltd., 57-61, Clerkenwell Road, E.C. (3). The electric light; any simple arc light arrangement will do, as the exposure will be short, or the Nernst high-power lamp.

**STUDIO.**—Would you be so good as to enlighten me on a few studio queries? I am thinking of building the studio for professional portraiture. What size would you recommend for best work? I have plenty of room at my disposal. I thought one about 30 ft. by 15 ft., or do you think a smaller one, in length, would answer the purpose? Would a three-quarter span roof be preferable to a half-span roof. Here again, I have plenty of light at my disposal, the situation being very open. Do you think a portable studio would be an advantage over a stationary-constructed studio, and just as reasonable in price? Which would be the best position for glass side of studio to face? If north, or north-east, what colour blinds would you recommend for top and side? Could you recommend a book or studio building?—**STUDIO QUERIES.**

The dimensions given would be excellent for professional purposes. A half-span roof, with this width, would be quite as good, if not better, than a three quarter one. As regards a portable studio, you would be able to take that away in the case of your removal, but if it were made a permanent building you could not. A local builder will give you an estimate for the two forms. Either north, or north-east, would be a good aspect. Medium green or dark blue blinds would be suitable for either. Bolas's book on "Studio Construction," published by Marion and Co. Price, 2s.

**DESPERATE OPERATOR.**—We do not think there is any doubt as to the cause of the spots on your postcards, and that they are due to metallic particles of some sort in the washing water. We can only suggest that you flush the meter and pipes thoroughly so as to clean them. It is quite possible that immersing the prints in salt and water after fixing would help you. We presume you are not washing too long.

**CURIOS KEW.**—We will comply with your request in due course.

**FINISH HUDD.**—(1). "Retouching," by R. Johnson, published by Marion and Co., 22-23, Soho Square, London, W. (2). No.

**RETOUCHING.**—I respectfully beg for your consideration as far as to answer me one or two questions in knife-work in retouching. I cannot get along with it at all, and I am anxious to know if I am doing the thing in the right way. I have in my possession two surgical scalpels and two patent affairs in the pencil-cases, points which are absolutely rotten, or else I don't know how to use them. Can you give me a few hints, or tell me if I can buy a book with the information in?—**TOM W. WILKINSON.**

The chief points to be observed in knife-work are, viz.:—To keep the edge of the knife itself properly set, holding it at the correct angle, and to make the strokes properly and in the right direction. Presuming that your surgeon's scalpels have been correctly ground for retouching purposes, the setting may be accomplished on an oiled stone, finishing off upon a good razor strop. The edge must be without the slightest "burr" on either side, as sharp as a razor, and perfectly free from gaps and irregularities. If the knife picks up the film or scratches, it is not properly ground or set. The angle at which it should be held to the film is nearly 90 degrees (right angles), but inclining slightly to the left. Different kinds of strokes are used, most of them being light, oblique ones from right to left. Whiting's book on

"Retouching" (published by Dawbarn and Ward, Ltd.), explains how to make, set, and use retouching knives.

**C. W.**—(1). Sharp and Hitchmough, 101, Dale Street, Liverpool. (2). The lens is an excellent one. Its aperture is not as great as one might be wished for portraiture, but it is a universal lens for outdoor and indoor work.

**STAND DEVELOPMENT.**—I should be glad if you will tell me if instantaneous exposures are best developed by stand development, and can you give me a good formula for rapid-shutter exposures (focal plane). I have tried glycin as advised in answer to "A.C.S.," but cannot get good results, except with fully exposed plates. What advantage is there in stand development over the ordinary way other than developing several plates at once?—**STAND.**

In stand development, as in other methods, a "long-factor" developer such as metol is best suited to instantaneous exposures. Rodinal with, say a little extra sulphite, will be found an excellent developer, using one part of the stock solution as purchased in 100 to 150 parts of water. The chief advantage of stand development is the facility of dealing with a number of all kinds of exposures at once without the need of constant attention.

**E. W. B.**—Certainly, it is possible, but the exposure is much longer. It is impossible to give a rough idea of the length, as we do not know the aperture of the lens, but if the latter is an R.R. working at f/8, the exposure will most probably run into several minutes unless the negative is an extremely thin one. We should advise you to get a condenser.

**INTERESTED SUBSCRIBER.**—(1). We are unable to account for the markings from the facts stated, but the cause must be, we should say, in some chemicals, inadvertently gaining access to the slab. (2). Kodak, Ltd., 57-61, Clerkenwell Road, E.C.

**URGENT.**—Any carbon tissue—see those advertised in our pages. The methods of toning bromide prints to the colour are not very satisfactory, and absolutely unfitted for commercial work.

**"STAINS OF C. C."**—Slow drying of the prints is one of the causes of such spots, and so is inferior blotters. Better not to use blotters at all. You should look up the letters on this subject which appeared in our columns in the latter part of last year.

**ROTINE.**—(1). Our own preference is for an amidol developed—the normal formula, such as that on page 976 of the "Almanac," diluted with twice or three times its bulk of water. Almost all the developers will give grey tones when diluted. (2). Equally permanent. (3). Soft negatives for preference.

**TINTING (Reply to Anxious).**—Your main fault lies in lack of strength and warmth in the shadows, and so your effect is rendered gradually flat and unconvincing. Darken with warmer colour the shadow beside nose, under the nostril and chin. With a cooler tone match the depression and form of socket under light side eye, so that it is in better balance with the other. If a heavier and warmer shadow is worked into the neck it will bring the face out to much greater advantage. The lights on the hair are too similar in strength. Wash a few folds and shadow into the drapery—it is all too white and glaring, and catches the attention to the detriment of the face, which you must always remember represent the point of interest, and that the dress and background are subsidiary only.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

A comparison of the cost of sensitive materials for half-tone plates it is shown that, per half-plate, the cost is 2½d. for dry 1½d. for collodion emulsion, and 1d. for wet-plate, against have to be placed differences in waste, etc., incurred in these cases. (P. 124.)

A German writer has attributed spots in collodio-chloride prints to chemical impurity of the baryta coating on the raw paper. (P. 124.)

Colour Photography.—An appreciation of the forthcoming process of one-exposure one-plate colour photography is given from the pen of M. Leon Vidal, who writes after a visit to the factory at Lyons. (P. 125.)

The meaning and method of ascertaining the "inertia" of a plate is the second article on sensitometric tests of plates by Mr. Kenneth Mees. (P. 125.)

The Photographic Convention, to assemble at Southampton in July, have presented to it a series of eight papers, will undertake a number of attractive short excursions, and will celebrate its centenary in company with photographic visitors from the Continent. (P. 129.)

An American photographer's scheme of making business during the winter season is reported on p. 128.

Some interesting side-lights on the canvassing system and on the use of picture postcards were thrown during the hearing of two last week. (P. 129.)

The annual meeting of the Royal Photographic Society passed off successfully on Tuesday last. The officers elected for the current year are announced on p. 135.

The new chamber dark-room lamp, developers for films and plates, and a system of electrical long-distance photography are among the subjects of the week. (P. 132.)

## EX CATHEDRA.

### Colour Photography.

The exhibition of colour photography at these offices, which has now two more weeks to remain open, has brought us many evidences of the practical and business interest which is being taken in the subject. We have had instances of professional photographers who have convinced themselves that in the immediate future photographs in colours will be required of them, and are preparing themselves for the task. More than one retoucher for the profession has made it his business to inquire how far his special work was likely to be utilised in making sets of three-colour negatives, and we have met with other technical photographers who have already made arrangements to supply three-colour prints of such subjects as flowers and fruit to wholesale horticulturists, and of vegetable produce to large seed merchants. The exhibition also has brought us in touch with several inventors of processes of colour photography, from certain of which more may be heard before long. The complete outlook at the present seems to presage the imminent establishment of colour photography among the strictly commercial photographic processes.

\* \* \*

### An Artist as President.

The Bristol Photographic Club have for their president Mr. John Fisher, Hon. A.R.C.A.Lond., a gentleman who is an artist by profession, and not a photographer at all. Mr. Fisher regularly criticises the monthly portfolio of the club, and gives an annual address, in which he reviews the work done in the previous twelve months. In this year's address he specially warned would-be pictorial photographers against "harshness" in their prints, and the absolute necessity of getting a feeling of "atmosphere." The members find this outside criticism very valuable, and other societies might do well to follow the same lines.

\* \* \*

### Indecent Postcards.

Most persons will be pleased to learn that the police authorities are now taking vigorous action against shopkeepers who vend picture postcards of an improper character, and that magistrates are inflicting heavy fines upon the evil-doers. On Saturday last a man appeared on a summons at the Marlborough Street Police Court for selling improper postcards, and the substantial fine of £25 and costs were inflicted. The cards were ordered to be destroyed. A few fines of this kind will no doubt act as a warning to others and put a check on this abominable trade, for it will take the profit on many thousands of cards to realise £25, with the costs in addition. During the hearing of the case the defendant's solicitor remarked that it would be a good thing if the authorities would prosecute the publishers

of these cards. This is precisely the view we have expressed on more than one occasion, and there would, we should say, be little difficulty in discovering them. It is a surprise to us that shopkeepers should show such things, or even have them on their premises. Quite recently we saw in a shop window not far from Blackfriars Bridge some cards of a most objectionable description. Productions of this kind will certainly bring the picture postcard into disrepute.

\* \* \*

### The Keeping Properties Of Collodion Paper.

It will doubtless be remembered by all our readers that towards the close of last year some correspondence appeared in our pages with regard to the occurrence of spots on C.C. prints. In the current number of "Die Photographische Industrie," a German trade paper, there appears an article by Karl Buisson, in which he details his experiences as regards the keeping of collodion paper before printing, which, whilst it does not seem to us to throw any light upon the formation of the yellow spot on the finished prints, may be of sufficient interest to record. The author points out that, by keeping, the back of the paper in nearly all cases becomes more or less grey or yellow. One firm of paper-coaters submitted samples of the raw baryta paper to the author for testing, and, though the paper was reported to be pure, it was found that after storing it for three months, it did not keep so well when coated with the collodion emulsion as at first. The baryta was then tested, and a sample of technically pure barium carbonate was found to be richly contaminated with sulphides. The author expresses the view that these bodies were produced by the use of sodium sulphate containing sulphuric acid to precipitate the barium from its nitrate or chloride, and the subsequent reduction of the sulphate to sulphide, during the dry process. But the highly stable character of barium sulphate is against such an explanation. The author may be right in his finding of sulphides, but they are certainly not produced in the above manner under ordinary conditions of preparing baryta paper. It is alleged, as to the yellowing of the unused paper, that the acid emulsion acts on the sulphur compounds and thus gives rise to sulphur compounds of silver. This may be one of the explanations of the trouble, but we would also point out that most, if not all, gelatines are bleached with sulphurous acid, and that it is very rare to come across a sample of gelatine free from the same. Naturally this defect cannot be obviated by the users, but manufacturers can insist on baryta papers being free from sulphurous acid and sulphides.

\* \* \*

### Placing of The Portrait.

One of the commonest defects met with in the portrait work of beginners is the incorrect placing of the picture on the plate. The most obvious mistake is the leaving of too much space above the head, which usually dwarfs the figure, conveying the suggestion of a short person. This is not only the case where a half or three-quarter length is being produced, but applies with equal force to head and shoulder pictures. The head is the highest part of the human figure, and even in a vignette if a good deal more space is left below than above the face, one feels that it might have been occupied had the artist desired it. The decorative effect of a portrait is much greater when the space at the command of the photographer is properly occupied, no part being left empty-looking and no part overcrowded, while the various parts should be properly held together by lines,

the character of which largely depends on the sex and individuality of the sitter. The portraits by Mr. Alvin Langdon Coburn at present on view at the R.P.S., 68 Russell Square, W.C., are very suggestive from this point of view, and while a superficial examination by older fashioned professional workers might lead to the idea that mere eccentricity was practised as a means of attracting attention, we think a little careful attention and thought will in most cases discover a satisfactory reason for what has been done. At all events, we would counsel such tolerant and sympathetic inspection of the work, for we think that though it is too individual in treatment for the everyday sitter at present, there are many points to be learned from a study of it which would have a practical everyday use. We say a "tolerant" inspection, because so much is lost by passing over what is not understood with a half-contemptuous disdain. Work, the qualities of which are obvious at a glance, is usually work which ceases to interest very soon. There is nothing vague or obscure in Mr. Coburn's portraits, and that is why we suggest that an effort should be made to find out why any particular treatment has been adopted.

\* \* \*

### Treatment in Portraits.

We may perhaps assist some of our readers in that study of Mr. Coburn's work to which we are urging them if we slightly indicate what is meant by treatment of a subject. Suppose photographs are required of an oak tree and of a silver birch. To the oak we assign the attributes of strength, vigour, and sturdiness, and so our negative would be fairly sharply focussed and fully developed, and our print a vigorous one on a rough surfaced paper. We should prefer to photograph the tree when not in full leaf, possibly during the winter, when the gnarled branches, giving evidence of stress and storm, would be most prominent. On the other hand the silver birch is the "lady of the woods," with its delicate tracery of fine twigs, its little twinkling leaves, and its silvery grey bark. This negative should be one with delicate contrasts of light and shade, the definition good, but not too perfect, lest the feathery effect of twigs and leaves be lost, and wiriness obtained. The print might be made on a smooth paper in a pearly gray tone of carbon, or on a smooth black platinotype paper. In this way the character of the print is in keeping with the character of the subject, and no inharmonious note is struck. It is quite recognised by most portrait photographers that the lighting suitable for the strong head of an old man is not at all appropriate to the rounded contours of a little girl, but we think the principle of appropriate treatment might be carried much farther than it often is. The omission of glaring incongruity is, after all, a negative quality, and much of the portrait photography of the present day would be vastly improved by the introduction of positive qualities.

\* \* \*

### Postcards.

The figures of postcard sales published in our last issue doubtless proved instructive reading to many readers, and particularly to those who have put the question to us as to the charge they should make for the right to reproduce their photographs in postcard form. As we have often pointed out, it is to the photographer's interest to take the production and supply of cards intended for local sale into his own hands. He will find it a sale a profitable side line, and his name on every card will mean a certain amount of advertisement of distinct value to him. He need not necessarily actually make the card himself. Collotype and half-tone postcards are printed at a low cost from photographers' negatives, as also

omides. The latter description of card, however, can-  
l should, be made by the photographer's own staff, a  
ck being accumulated in spare time for the season's  
es. Obviously, if a postcard publishing firm finds it  
th while to purchase rights of reproduction in al  
views, it will pay the photographer to look after the  
iness himself and supply the stationers and other trades-  
n in his town. A publishing firm seeing proofs of  
activity in this direction in the windows of  
stationers will probably not move further in the  
ter, and the local publisher will be left with the trade.  
happen to know of the surprise which postcard publish-  
firms have felt at photographers' lack of enterprise in  
ering the local competition field.

\* \* \*

**phide  
ling.** Considering the degree of popularity  
that this method of toning has attained,  
seems to us that an investigation of the actual results  
the process is highly desirable. There are several  
btful features that require elucidation, as will be seen  
reference to Dr. Chesterman's letter in our issue of  
uary 19, and to Mr. E. J. Wall's article on the use of  
zol, which appeared on February 2. It seems to be  
monly assumed that the result of the sulphiding pro-  
is the conversion of the silver into silver monosul-  
le, which is well known to be a very stable compound.  
process as usually carried out is a very rapid one, so  
d that there is much reason to doubt if anything more  
a very partial conversion takes place. Further, there  
other possible sulphides beyond the monosulphide.  
Chesterman states that "rapid toning causes the forma-  
of a silver sulphide which is not the monosulphide,  
yellow whites and half-tones and rapid fading are the  
lt." Mr. Wall has noted that the new reducer "San-  
appreciably affects the toned image, and others, we  
ve, have observed similar effects with different  
cers. As silver monosulphide is somewhat readily  
ised it is not difficult to understand that a reducing  
tion may affect the sulphide in the image, at the same  
it is possible that the effect of the reducer is due to  
ylent action on residual silver salts. The complete-  
of the sulphuretting action may perhaps vary with  
silver salt to which the sulphide solution is applied,  
it is not impossible for sulphur to be deposited in the  
hiding process. Dr. Chesterman advises that the sul-  
ing process should be continued for at least a quarter  
hour in the case of fixed P.O.P. prints, and it appears  
that it would be as well to adopt the same precaution  
bromide prints. If complete action is possible the  
onged application of the sulphide solution is most  
ably necessary to secure it, but we are so much in the  
as to the actual mechanism of the process that all  
are more or less rules of thumb. More definite know-  
e of what really happens is therefore distinctly desir-

\* \* \*

**Iris  
phragm.** An important practical matter often ig-  
nored by photographers is the existence  
backlash" in the iris diaphragm. In many cases the  
of any particular aperture varies according as you  
p down" to it or "open out" to it, and the variation  
ually enough to affect exposure materially in the case  
he smaller apertures. We have just had occasion to  
this matter in three different lenses. No. 1 was a  
ern anastigmat of the highest class by a German maker  
reat repute, No. 2 was an old type of rectilinear by a  
known English firm, and No. 3 was an old German  
igmat of unknown make. No. 2 was the only one that

revealed no backlash, and this had a metal iris with very  
exactly fitting moving parts, and was, moreover, fitted with  
a spring catch acting at each aperture. No. 1 revealed  
more backlash than was expected after examination of its  
very perfect workmanship, and it is quite possible that the  
defect in this case was due to the binding of the leaves,  
which appear to be of vulcanite. As no catch was pro-  
vided, at least three separate measurements were made for  
each aperture, and wherever an error of over one-tenth of  
a millimetre was detected fresh readings were taken. A  
maximum and minimum value was found for every aper-  
ture, but the differences proved to be negligible in all aper-  
tures except  $f/32$ , which had a maximum value of  $f/32.4$   
and a minimum of  $f/36.3$ , the measured difference being  
four-tenths of a millimetre. The aperture marked  $f/16$   
varied only from  $f/16$  to  $f/17$ , and that marked  $f/22$  from  
 $f/21.8$  to  $f/23$ . No. 3 lens had a very badly made iris, and  
the apertures were marked with mysterious numbers that  
could not be identified. The smallest aperture, marked 72,  
varied from  $f/41.3$  to  $f/50.7$ . The next smallest, marked  
48, varied from  $f/22.5$  to  $f/25.8$ . In the one case the expo-  
sure variation was approximately 2 to 3 and in the other  
as 10 to 13, the error of the smallest stop being un-  
pleasantly large. Obviously, when using an iris, it is  
advisable always to make the adjustment in one direction.  
Stopping down, when possible, in preference to opening out  
to any particular aperture.

\* \* \*

#### The Accurate Marking of Apertures.

In the experiments previously described  
upon backlash a very unsatisfactory  
state of things was noted in regard to the  
accuracy of the markings. In lens No. 1, stops  $f/8$ ,  $f/11$ ,  
and  $f/16$  were accurately marked, and so were  $f/22$  and  
 $f/32$  if we make allowance for error due to backlash. But  
 $f/45$  turned out to be really  $f/48$ , while  $f/6.8$  was only  $f/7.2$ .  
There is no doubt as to the accuracy of the measurement  
of the largest aperture, as no less than seven determina-  
tions were made at different times, while the accuracy of  
five out of the seven apertures proves the correct adjust-  
ment of the apparatus. The error in this largest stop may  
be justly styled inexcusable in a lens of such a class. In  
the English No. 2 lens the full aperture of  $f/5.6$  was correct.  
As the iris was found free from backlash the measurements  
were not repeated, but those obtained were  $f/7.5$ ,  $f/10.3$ ,  
 $f/14.7$ ,  $f/20.6$ ,  $f/32.5$ , and  $f/39.4$ . It is remarkable that  
most of these are larger than the marked apertures,  $f/8$ ,  
 $f/11$ ,  $f/16$ ,  $f/22$ ,  $f/32$ , and  $f/45$ ,  $f/32.5$  being an insignificant  
exception. The error in the smallest aperture might be  
inconvenient, as there is a considerable difference between  
 $f/39.4$  and  $f/45$ . From these experiments we may learn  
that time spent in testing apertures will, in perhaps too  
many cases, be time well expended.

\* \* \*

#### A New Aspect of Depth.

In the current number of "Knowledge"  
Dr. S. H. Bryan, F.R.S., draws attention  
to a simple rule for estimating the defini-  
tion that will be obtained on near objects when the camera  
is focussed for infinity. Briefly, it is this:—Assuming  
sharp focus to be secured on infinity, then any two points  
on a near object will be separately represented on the  
plate, provided the distance between them is greater than  
the diameter of the stop. If the distance between the two  
points is equal to or less than the diameter of the stop their  
images will merge into each other or overlap. This is, of  
course, quite correct. It is an undoubted fact that if the  
aperture has a diameter of, say, one inch, then any two  
object points separated by a distance greater than one inch  
will be separately represented on the plate, whatever their

distance may be from the camera. The separate images will, however, only be sharp when the object is beyond a certain distance. If near, both images will be blurred, and though they will never merge into each other, they will undoubtedly merge into the images of intermediate object points. If the object consisted of a series of separated points we could understand that the rule would be a useful one. It would only be necessary to know the minimum distance between the closest dots, and to stop down until the diameter of the aperture was somewhat less than that distance, to ensure the separate representation of every dot. But, considering that natural objects are not made up in this way, we confess we do not quite see how the rule is to be usefully applied in practice, though Dr. Bryan says that he found it to be of great service on his recent trip to South Africa. He gives a second rule for use when the camera is focussed on a near object, but in this case, as in the other, we fail to see the mode of application. We are inclined to think that we have heard of similar rules to these before, and it would appear that they agree practically with the old theory that considered depth to vary with aperture alone. The result of looking at the matter of depth from this point of view is that while the amount of confusion produced is always proportional to the scale of the image (which is a somewhat doubtful advantage), there is no set standard of depth to base calculations upon. The theory is all right, in theory, but in practice it is somewhat vague and unsatisfactory. It is true that depth is itself a vague and unsatisfactory subject, as the real facts seldom agree with estimations, but, for all that, we consider the most workable method of estimating depth is the usual one based upon a fixed amount of allowable confusion.

#### DRY PLATES, COLLODION EMULSION, AND WET COLLODION IN PROCESS WORK.

It is sometimes a matter of controversy as to which is the more economical negative-making material in photo-engraving, dry plates, collodion emulsion, or wet collodion. There are several factors to be taken into consideration, though the cost of material is the most obvious.

We may take as unit of size the half-plate (i.e., 12 by 16 centimetres, or 192 square centimetres), inasmuch as the larger portion of photo-engravers' work could be done on this size. Often it is not, where wet plates are used, but a larger size taken when the work is of such a size as to approach the edges of the plate. Larger sizes, however, will be more costly, though not quite in proportion in the case of emulsion and wet plate, but a little dearer relatively in the case of dry plates, the standard price of which for dry plates is 2s. 3d. per dozen. We take no account of possible discounts in either material.

Coming now to emulsion, a litre costs 25s. Taking three ccs. to cover a half-plate, this quantity will cover 333 plates. We have not been able to use less quantity of emulsion than this with ease, though M. Calmels, in "Le Procédé" for October, 1905, says that a litre should cover 8 square metres (i.e., or 416 half-plates). However, taking it at 333, the cost is .72d. per plate. To this must be added the cost of glass. A reasonably good glass, not patent plate, will cost 2d. per piece, and though this can be used again and again, it costs something in labour to prepare it, which must be considered, and some allowance must be made for wear and tear. Perhaps it would be fair to say cost of glass and the value of the time occupied in

coating the emulsion plate would not be less than making a total of, say 1½d. per half-plate. This is a saving of 1d. on the dry plate; against this, however, must be put the larger amount of waste with emulsion, firstly, from the frequency with which a larger plate would be used than would be thought necessary with a dry plate, and, secondly, from greater variations in the film than are found in the dry plate of commerce.

Turning now to wet collodion, the standard price for iodized collodion may be taken at £1 per Winchester quart, which equals 8s. per litre. We may again take 3 ccs. necessary to cover a half-plate, though Dr. Eder quotes Kleffel (Ausführliches Handbuch, page 232) as saying that 2 ccs. will cover 13 by 18 cm., i.e., 234 square cm., but from our experience it will generally take a little more than 3 ccs. for 192 square cm. Then the silver bath must be considered. A plate put into the bath, and withdrawn, will take with it from 1 cc. to 1½ cc. of solution. To be liberal, let us say, 2 ccs., and let us assume that the bath contains 10 per cent. silver nitrate. In comparison with the solution used up, the amount of silver nitrate converted into silver iodide may be neglected. Then 333 plates, which one litre of collodion will cover at 3 ccs. per plate, will take 666 ccs. of bath, that is 66½ grammes of silver, or roughly, 2½ ounces. Reckoning silver at 1s. 8d. per ounce, the cost is 4s. 2d. Add to this the 8s. for collodion, and equals 12s. 2d., which gives per plate .43d. Now to this must also be added the cost of glass and the value of the time taken in sensitising the plate. This cannot take less than five minutes per plate, and if performed by the skilled operator himself, as the coating with collodion emulsion would be, costs at least 1d. per plate, but inasmuch as it is done in most houses by apprentices or learners, it is perhaps not fair to reckon more than we did for emulsion on this account, namely ½d., or, roughly, say wet plate costs 1d. per half-plate. Since the time of sensitising (or coating in case of emulsion) is the same whatever size is used, this cost will decrease in proportion on this account.

Our next question is: Is there any difference of expense in manipulation? In exposure the advantage will rest with the dry plate, therefore there is some saving in electricity current and in cost of the labour. In the after-treatment of the plate, if the work be done in batches, the advantage rests with dry plates because they can be dealt with in numbers in big dishes, while emulsion or wet plate must be treated individually. If, however, individual jobs have to be done, then dry plates take somewhat longer, though in skilful hands exceedingly little. The cost of chemicals may be disregarded, as though dry-plate developers may be slightly dearer, chemicals will not need to be used so frequently in intensifying, or may be cheaper than those used in wet plate.

As to results, the wet-plate worker will say that nothing can equal his process, but results from dry plates leave little to be desired, when once it is understood how to get what the dry plate will give.

From the above consideration it would appear that the wet plate is the cheaper process, but, on the other hand, everyone knows of baths going wrong, of spots, comedoes, oysters, of dirty glass, and other wet-plate troubles, while for the time being are a source of worry to the operator and expense to the employer, and there are probably more certainty and fewer repeat exposures in an establishment that has systematised the use of dry plates, which must largely balance the cost of this material. In any case, it should be remembered that the cost of material in half-tone work is a small proportion of the total. It was recently stated by Mr. Arthur Cox (a dry-plate user, we believe) that he estimated it did not exceed 10 per cent.

## ANOTHER FACTOR AFFECTING DEPTH.

we disregard the effects of aberration and of inconstancy of aperture, it is apparent that the depth available with any particular lens must be governed by the angular aperture of the light pencils forming the image. Angular aperture is, indeed, the only factor commonly taken into consideration in calculations concerning depth; but it is generally forgotten that these calculations only consider the angular aperture from an arbitrary and unpractical point of view. The existence of Gauss planes is assumed, and this assumption compels us to regard the intensity of the lens (or ratio of aperture to focal length) as equal to twice the tangent of half the angular aperture. As a matter of fact, this is not the case, excepting in very unusual conditions. The actual existence of Gauss planes is avoided as far as possible by the lens designer, who aims at fulfilling the sine condition, which condition introduces an approximately spherical virtual refracting surface instead of a

plane one. If the focus is the centre of this spherical surface then the intensity equals twice the sine of half the angular aperture instead of twice the tangent, which means that the angular aperture is increased and the depth diminished. It is, therefore, possible for two lenses of equal intensity to have different angular apertures, and on that account to show different qualities as regards depth. Thus a very highly corrected anastigmat in which the sine condition is fulfilled must show less depth than another lens in which that condition is ignored. In the case of a single landscape lens the virtual refractive surface may even be convex to the image, and in such a case the angular aperture is diminished, and the axial depth attainable may be increased beyond that allowed for by calculations.

It does not appear that this factor alone is sufficient to account for the considerable difference commonly observed in the depth given by anastigmats and rectilinears, but it must certainly be a contributing cause of variation.

C. WELBORNE PIPER.

## COLOUR PHOTOGRAPHY.

### THE LIPPMANN AND LUMIÈRE PROCESSES.

in arranging the exhibition of colour work, the Editors of THE BRITISH JOURNAL OF PHOTOGRAPHY desired to show a specimen of the new method of obtaining colours direct, as described last year by M. Lippmann (see B.J., June 30, 1905). M. Lippmann, who, as is well known, is excessively modest, invited to send a specimen, for although the results were obtained by a new method, he did not think it of such relative importance. I made an appointment with him to insist on interest which the BRITISH JOURNAL attached to being able to show a specimen of this last research. As I pointed out to M. Lippmann, the process may not be of practical importance at present, but it would be well to show that one may have an effect of interference with transparent sensitive films of various kinds, with bichromated gelatine as with the others. It should be noted here, that the results given by a film of bichromated gelatine show extremely brilliant colours, and exhibit very clearly the complementary colours when viewed by transmitted light.

This fact should be of importance immediately we have a film which will give us the desired result at a very short exposure.

It must not be forgotten that bichromated gelatine is in every way orthochromatic on the one hand, and on the other that its sensitiveness to the light reflected in a camera is very low, which means that the exposure is very long. These two conditions, however, only attract further notice to M. Lippmann's experiments, as the forerunner of more practicable methods.

From the fact that the complementary colours could be so easily seen by transmitted light, M. Lippmann concluded that it would be possible to print by contact in a printing frame results which showed this particular character.

It is known that practically white and black are reciprocally complementary. Every positive printed under a black and white negative is its complementary in white and black. In the same way, every colour seen by transmission is printed in its complementary on plates which have the necessary panchromatic qualities.

Some day we shall certainly reach this stage. In science nothing is negligible, and it should be known that M. Lippmann, with all his modesty, is always trying to perfect his

discovery of photography in colours by the direct method, by the photographic production of thin luminæ of a wave length equal to that of the vibrations of the natural colours.

### The New Lumière Direct Process

As regards the Lumière process, we have quite another thing. In one word, we have the three-colour reproduction of colours, but with one exposure and on one and the same sensitive plate. On a journey to Lyons at the end of May last year, I had occasion to see MM. Lumière, and they were good enough to show me the results of their first trials. I admired stereoscopic views, lantern slides, also 13 by 18 cm. transparencies viewed directly by looking through them. My impressions were such as cannot be expressed except by superlatives. I certainly did not expect such a bewitching spectacle of pictures so sharp, true to colour, and at the same time so striking.

Evidently we have here actually the process of the future for everybody. That every reader of the BRITISH JOURNAL may know what this process is, it will be as well to recapitulate its principles. By the aid of the minute grains of potato starch, suitably separated, and coloured red, orange, violet, and green, MM. Lumière have produced on one plate a multiple screen. The coloured starch grains are sifted over the surface of the plate, so that there are from 40 to 50 grains to the millimetre. The result is that one has a plate covered with an infinity of trichromatic colour filters.

If on a plate thus prepared the white interstices be covered with a black powder and the film be then insulated by a convenient varnish of the necessary refractive index, and if an emulsion, as free from grain as possible, be then coated, nothing more is required to obtain an image in colours than to place this plate in the dark slide in the camera, with its glass to the lens, and to expose and develop as usual. This development, however, must be supplemented by a reversal of the image, the negative must be converted into a positive, and one then has a polychrome image which renders absolutely the true tints of the original. I was absolutely astounded at the numerous results which were shown me. One must necessarily consider the extreme delicacy of manufacturing such a plate. These plates with multiple screens evidently constitute a difficulty, the industrial solution of which would appear to us to

be insurmountable, if it were not in the hands of investigators as wise as they are ingenious. I am absolutely convinced—time will prove the truth of my prediction—that they will be overcome, and that MM. Lumière are equally confident it is shown by the fact that they have undertaken the construction of a special factory for the construction of these plates.

### THE JUMEAUX PROCESS.

SOME words of explanation are due to Dr. B. Jumeaux in reference to the exhibits by himself, Nos. 12–17, in the present exhibition. By a misapprehension of the description of the process sent by Dr. Jumeaux, one example was described as a two-colour result. Space did not permit of our giving in extenso in the catalogue the description of the method which should be identified with these particular exhibits, but we may do so now. The copy of the portrait of the King, made on the Cadett "Spectrum" plate with Sanger Shepherd filters, was printed by the following process:—An opal is printed from the red sensation negative, washed, dried, and resensitised, after which it is printed under the green screen negative.

By this process we should have pictures which could only be viewed by transmitted light, or projected by means of lantern, or seen in the stereoscope. But we do not despair of seeing MM. Lumière discover a process by which the colour photographs first taken could be multiplied indefinitely.

LEON VIDAL.

When sufficiently printed it is washed in a solution to get completely rid of the sensitiser, then washed and stained red. It is then allowed to stand in running water until just enough colour is left to complete the picture, when the yellow was placed over it. The red colour is only retained where light has affected the film through the negative and in proportion to this action.

The yellow image is made by fixing out a plate or film which, after sensitising and drying, is printed under the blue screen negative, after which it is treated as was the red, except that the dye used is yellow.

In the case of the other prints, the base is bromide paper stained blue with films stained red and yellow superimposed.

## THE INTERPRETATION OF SENSITOMETRIC TESTS.

### II.—THE INERTIA OF A PLATE.

In order to express the properties of a plate the following constants have been found useful in practical work. It is necessary that, as far as possible, all the properties should be expressed in numerical constants. For instance, the statement that one plate is "soft-working," while another "gives density easily," is far less satisfactory than the statement that their respective  $\gamma$ 's, for example, are 1.6 and 3.55, because this last method of expression makes comparison much easier, even though no attention be paid to the relative accuracy of the two methods of expression.

The constants which appear convenient for practical purposes are:—

The Inertia dealing with the sensitiveness.			
$X$	"	"	colour sensitiveness.
$\gamma_{\infty}$	"	"	density giving power.
$\kappa$	"	"	velocity of development.
$tv_1$	"	"	speed of development.
(Note.—These last constants are not identical, as is explained later.)			
$O$	"	"	latitude.

Three other measurements of importance should deal with the fog, the grain, and the accuracy of coating.

#### The Inertia.

The inertia of a plate is the insensitiveness of the plate. It is practically found in the following way:—If we expose a plate to a single source of light for a series of differing times, and then develop it, we shall get a number of blacknesses corresponding to the different exposures. If now we optically measure the amount of silver which corresponds to each of these blacknesses we may construct a curve by plotting on a piece of squared paper the amounts of silver (usually termed densities) against the exposure. If this is done, it is found that a large portion of the line so obtained will be a straight line, if, instead of the exposures themselves, we use their logarithms. For instance, if we give exposures of 1, 2, 4, 8, 16, etc., candle-metre seconds, their logarithms will be in the proportion 0, 1, 2, 3, 4, and so on. Thus, taking an actual example, last season the Barnet Red Seal plate was tested for THE BRITISH JOURNAL OF PHOTOGRAPHY, and one of the plates measured then gave the following readings:—

Exposure.	Log. E.	Density.
10	1.0	2.80
5	.70	2.27
2.5	.40	1.65
1.25	.10	.992
.625	-.80	.600
.3125	-1.50	.280
.156	-2.20	.127

The exposures are given in candle-metre seconds. A candle-metre second is the measure of the amount of light received by one metre distance from the standard candle in one second. If the light be half a metre distant instead of one metre, it will have an intensity of four candle-metres, since the intensity of a light (for a small source) varies inversely as the square of the distance.

The method of exposing is by the use of a sector which gives exposures each of which is half the preceding one. If, then, we plot these figures as shown in Fig. 1, we shall

Fig. 1.

obtain a line which consists of two curved portions and a straight central portion, in which the points are approximately in a straight line. Joining these central points and producing the line so obtained to cut the axis, we term the exposure corresponding to the cutting point the inertia of the plate; thus in Fig. 1 the logarithm of the inertia is  $\tau.64$ , corresponding to an inertia of .408.

Since the smaller the inertia the faster the plate, inertias are usually expressed by dividing the inertia into some number and giving the result as the sensitiveness number.

### Light Sources.

Before we discuss this sensitiveness number, it is necessary to consider the light source employed for finding the inertia, because the value of the inertia obtained will depend on the light source employed. Messrs. Hurter and Driffield originally used the British standard candle as their standard light source. This candle has, however, generally given way to the pentane standard, which is defined as the light given by a flame of fixed dimensions produced by burning air which has been drawn over a fixed surface of pure pentane. While the pentane standard forms a convenient primary standard, it is not at all convenient as an actual working light source, because regulation is frequently necessary; and, moreover, pure pentane is expensive. So that in practical sensitometry various secondary standards are used, and it appears to be due to this fact that the measurements which are made of inertias differ so greatly.

As far as I know, the following primary and secondary standards are being, or have been, used in practical sensitometry:—The amyl-acetate lamp (Hefner-Attenneck); the benzine standard (the Scheiner standard in Germany); the Carcel standard (in France); the Vernon Harcourt pentane standard; the fish standard candle; electrical glow lamps (either controlled by a rheostat or not controlled); the crater of an incandescent arc; acetylene flames (screened and unscreened); flames (screened and unscreened); magnesium wire and lamp; phosphorescent tablets; daylight, in conjunction with an actinometer. Until some agreement is reached as to the standard, it is clearly impossible to hope for agreement in the inertias of plates.

The standard adopted for the sensitometric tests given of plates in THE BRITISH JOURNAL OF PHOTOGRAPHY consists of a screened acetylene burner, which is modified by means of a blue screen, so that it has a spectral composition in approximate agreement with that of daylight (necessary in order to avoid errors in testing orthochromatic plates; for details see "Phot. Jour.," November, 1904), and this acetylene burner has been calibrated against the mean of two standard pentane burners of different makes, which agreed to 2 per cent.

Readings of inertias made upon this standard agree very well with each other, and also with the results obtained upon other burners of the same type which have been calibrated against it—for example, that used at Harrow by Messrs. K. & L. Ltd.

### The Sensitiveness Numbers.

Messrs. Hurter and Driffield, for practical use in the actinometer, expressed the results of their tests by means of numbers obtained by dividing the inertia into 34; so that the actinograph

expression  $\frac{34}{\text{Inertia}}$  This is what ought always to be meant by the expression H. and D. No.

It must, however, always be remembered that this value depends on the light source used, and the statement that a plate has a H. and D. No.  $\alpha$  does not always imply an absolute test. As a matter of fact, plate makers are, I believe, hampered by the publishing of speed numbers, because of a quite erroneous popular impression that a faster plate is necessarily better than a slower one. There are even stories of plates being issued with an ascertained speed-number being found to be unsaleable because that speed-number was slightly less than that given by a rival plate, which in reality was no different, and then being re-issued with a different label and an altered speed-number. The number adopted by Mr. Watkins for his P number is obtained by him by doubling the H. and D. numbers he finds. But Mr. Watkins usually gets rather lower H. and D. numbers than I do, and I find that I get a better agreement with his P number by dividing the inertia into 50.

The F values given by Mr. Wynne appear to be the square root of the Watkins number multiplied by 8.

### Accuracy.

The accuracy of inertia determinations appears to call for notice at this point. Assuming the light source to be constant, there are two sources of error to be considered: (1) Errors due to the method of development used; (2) purely experimental errors.

(1) The question of the effect of the developer used upon the inertia obtained is a very difficult one to discuss, and I should like to say that any statements here upon this point are simply the results which I have obtained, and may at any time need to be modified after further evidence. In the first place, if bromide be present in the developer the inertia will depend upon the duration of development. This fact, which was first made clear by Messrs. Hurter and Driffield in 1898, is exemplified in Fig. 2, in which a plate has been developed in a bromide developer for four, ten, and sixty minutes. The inertia gradually decreases as the development is continued, until it reaches the figure which would have been obtained if the plate were developed in a developer free from potassium bromide. Occasionally plates are found in which the potassium bromide has been left in the film itself, and

Fig. 2.

in this case the same phenomenon occurs. The inertia then can scarcely be said to have a definite value; that usually given is the value obtained when development is prolonged as much as possible.

If developers free from potassium bromide be employed, the reducing agent may, or may not, exert an influence on the inertia obtained. With many plates ferrous-oxalate always gives a higher figure than any organic reducer; with many other plates this is not so. I have never met a plate in which different inertias were obtained with different organic reducers, but I have had several examples of such plates shown me by friends. At any rate there are no definite constants which can be given to convert an inertia found with one developer into that found with another, and as a general rule all organic developers give the same inertia, providing that the concentration of the reducer is not too great. In the same way there appears to be no definite evidence for any alteration in the inertia produced by altering the temperature of the

developer. The developer most generally adopted for finding the inertia is probably that introduced by Messrs. Hurter and Driffield as a standard pyro-soda developer.

(2) Purely experimental errors. These, with accurate exposing and measuring apparatus, are due to (a) unevenness of coating; (b) the fact that a plate curve is not really a straight line at all, and that consequently the personal error in graphic plotting is considerable.

This last error amounts to about .01 on the log E axis for an evenly coated plate, which makes an error of about 2 or 3 per cent. on the inertia, but a slight unevenness of coating may raise this error considerably, and on commercial plates

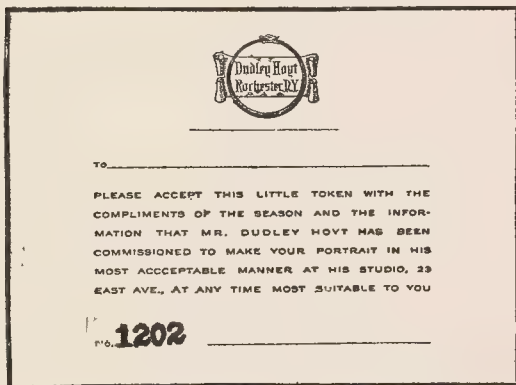

inertias are usually doubtful to at least 10 per cent. This for instance, two tests of a somewhat uneven plate may give 450 and 500 (a difference of only 10 per cent.) for the inertia. This explains the care necessary to obtain plates coated carefully as possible on patent plate for experimental work. It also shows the absurdity of choosing a plate marked 2 in preference to one marked 180 when there is no further reason for the choice. And, as I hope to show, the speed of a plate is by no means its most important property, even when the plate is being used in such a way, that, the retention of detail with the minimum of exposure is all-important.

C. E. KENNETH MEES.

## HOW A PHOTOGRAPHER "RUSHED" THE SLACK SEASON.

New wrinkles in advertising are always welcome to the progressive photographer, and when the wrinkle has been tried by a good business man and found profitable, it becomes doubly interesting. For this reason we may quote from our New York contemporary, "The Photographer," the account of a scheme adopted by Mr. Dudley Hoyt, a well-known and respected photographer, of Rochester, U.S.A., during a season when photographic business in America is very nearly at a standstill.

Briefly, the plan consisted in sending to a carefully selected list of names a circular and an engrossed card to be used as a presentation card or order for photographs at Christmas. The accompanying engraving is an exact reproduction, colour excepted, of the card used by Mr. Hoyt:—

The circular was printed in black and gold on thick Japanese tissue. The gist of the subject matter follows:

### Something New for Christmas.

A Holiday Suggestion from the Studio of Dudley Hoyt.

FEW GIFTS can compare in interest and future satisfaction with a present of an order for a dozen good photographs, and the pleasure that accompanies such a gift has a tinge of anticipation that lasts long after more material presents have been inspected.

To reduce the making of such a present to a practical basis the enclosed card, printed and embossed on vellum, has been prepared. To use the card simply fill in the name of the person you intend to present it to, sign it and hold it until Christmas. Then fill out the blank and send it to the studio at once.

The following brief descriptive list will be of assistance in selecting the class of pictures it is desired to present:

The price list, which included everything from baby pictures at \$8 a dozen to large carbon prints at \$100 each, was inserted here, followed by a few paragraphs headed "Special Notes":—

All of Mr. Hoyt's portraits are printed in platinum with the exception of Class H, printed in carbon, and every print is per-

sonally inspected and signed by Mr. Hoyt, no matter in what class.

Ample opportunity for modification in the selections will be granted so that absolute satisfaction to the recipient will be assured.

Additional cards will be furnished on request.

Special presentation cards for weddings and birthday presents can be supplied.

Specimen prints in all classes are on exhibition at the studio and additional information will be gladly furnished.

On the back of the four-page circular the following blank, bearing a serial number identical with that of the card which accompanied it, was printed:—

Note.—In filling in this blank, to be sent to the Studio, be sure to indicate the class desired. It is not necessary to place anything on the presentation card except the name of the recipient and your own. The number will be sufficient to identify the order.

(Cut this page off and mail to the Studio.)

No. .... Rochester, N. Y. .... 1906.

MR. DUDLEY HOYT,

23, East Avenue, Rochester, N. Y.

I intend to present the card numbered as above to M. ....

Please enter ONE and on

for ONE DOZEN of Class ....., for which I enclose my check

\$..... Please charge to my account.

(Strike out the line not used).

Name.....

Address.....

It will be seen that the plan differed from other Christmas schemes in that instead of the purchaser being obliged to call and pay for the order it was mailed him and laid before his or her eyes for several weeks before Christmas.

The card itself was a very fine specimen of printing and engraving and was enclosed in a tinted envelope with a plain, embossed design. The whole was enclosed in a large square envelope and sealed.

The expense of the campaign was summarized by Mr. Hoyt as follows:—

3,000 envelopes for cards.....	\$6.00
3,000 envelopes for mailing.....	4.50
Stock for cards and folder.....	42.00
Printing .....	24.00
Embossing (labour).....	10.00
Addressing (labour).....	4.00
Mailing .....	60.00
	\$150.50

The direct returns from the campaign to and including December 28 were \$1,968.00. To this will be added such orders as were received without notification to the studio.

The plan was not advertised in the newspapers, and indeed no notice was done to take away from the scheme the idea of exclusiveness.

It will be seen that Mr. Hoyt accomplished several very decided and interesting moves in the professional field. He has provided a fair measure of work for his force during a month in the year

red to be as dry, as far as business is concerned, as August; he planted a carefully-worded price-list in the homes of three hundred people and has called the attention of his people in an unusual manner to the value of photographs as Christmas gifts. A large proportion of the cards used," said Mr. Hoyt, "were wanted by members of the family who could not be persuaded under ordinary circumstances to visit the photographer. The cards were also liberally by young men who wished pictures of their best girls who adopted this method of securing what they wanted."

### THE PHOTOGRAPHIC CONVENTION.

PRELIMINARY circular of the proceedings of the 21st meeting of the photographic Convention of the United Kingdom, which will take place at Southampton in July, under the presidency of Mr. E. J. Humphery, M.A., has been issued by the honorary secretary, Mr. J. Bridge, East Lodge, Dalston Lane, N.E. The headquarters of the Convention will be the Philharmonic Hall, High Street, in which the meetings will take place and the exhibition be held. The programme will include a very representative display of modern apparatus, arrangements are completed for demonstrations of portraiture, printing by electric light and of other photographic processes. Colour photography will be made a prominent feature of the Convention. Sir William Abney has expressed his intention to exhibit a selection of his projection colour photographs. Mr. E. J. Wall is arranging an evening to be devoted to colour photographic printing processes, and it is hoped that MM. A. and L. Lumière will demonstrate their new direct colour process, of which M. Vidal is enthusiastically on another page this week, after a visit to the home of the Lumières at Lyons. Photographic record and the aspects of modern photography will likewise form part of the Convention.

The papers to be read at the evening meetings include:—

"The Differentiation of Bacillus, Coli Communis, and Bacillus typhosus, by Means of the Photographic Plate." By Mr. Walter C. Anderson.

"The Photographic Film Ionised on Exposure." By Mr. Henry J. B.A.

"Useful Negatives from Poor Ones." By Mr. C. H. Bothamley.

"The Ordnance Survey Department." By Colonel S. C. N. Grant, R.E.

"Old English Manners and Customs." By Sir Benjamin Stone.

"Clouds." By Mr. A. W. Clayden.

"Combination Printing." By Mr. A. Horsley Hinton.

"The Application of Cinematography to Natural Science." By Mr. F. Martin Duncan.

The excursions, we are glad to say, will be short, and will be arranged to leave ample time for photography. They will include to:—

Wessex, Carisbrooke, and (if possible), Osborne House.

Wessex, New Forest, Beaulieu, etc.,

Wessex, Winchester, and St. Cross,

Wessex, and the vicinity.

In addition, the members will have the exceptional privilege of using the department of the Ordnance Survey, an opportunity which is rarely afforded, and for which the thanks of the Convention have already been extended to Colonel S. C. N. Grant, C.M.G., R.E.

Attention should also be made of the unusual yachting facilities of Southampton, and of the fact that the President's "At Home," on Wednesday afternoon, will take the form of a yachting party.

Mr. Humphery's leisure for many years has been spent aboard his yacht, and, without anticipating the announcement of his plans for the entertainment of the Conventioners, on July 11, it may be said

that the occasion will mark the zenith of enjoyment in what promises to be a most enjoyable week. The Earl of Crawford also hopes to visit his yacht, "Valhalla," at Southampton during the Convention, and to take part in the meetings.

Finally, the "coming of age" meeting of the Convention is to be celebrated by the visit of a number of members of Continental photographic societies and bodies. The "entente cordiale" is to acquire a new meaning in photographic circles, by the presence of a large number

of photographers from France, which country, however, is not the only one to join English Conventioners in celebrating their 21st year of life. There seems every prospect of the meeting being the most notable one in the history of the Convention.

### ALLEGED POSTCARD FRAUDS.

A CASE which throws light on the business to be obtained in photographic picture postcards, came before the Shepton Mallet Petty Sessions on Friday, February 2, after adjournment. A photographer named Joshua William Humphreys, was charged with having obtained from Fred. C. D. Hurd, of Shepton Mallet, also a photographer, the sum of £2 7s. 6d. by false pretences, with intent to defraud. In September last the prisoner called on Mr. Hurd and solicited orders for picture postcards, representing that he could do them at £2 7s. 6d. per 1,000 for cash with order, or £2 17s. 6d. for cash on delivery. He stated that these low prices were due to his special arrangements with London firms, whose usual prices were known to be £4 10s. per 1,000. The prisoner had his photographic apparatus outside on a bicycle, and he agreed to take eight photographs of views to be selected by the witness, and supply a thousand postcards with these views for the sum named. Witness gave him a cheque for £2 7s. 6d. in order to take advantage of the discount. Prisoner gave a receipt, produced. He gave witness to understand that he had a large business in Blandford with assistants turning out several thousands of postcards per week. There was an address printed on the receipt. It was on the faith of these representations that he parted with his money. Prisoner showed him other orders he had had in the neighbourhood. Proofs were to have been sent in seven days. Witness would not give the order without the proofs. He did not receive the proofs, and wrote twice to the address given, without receiving a reply. Afterwards he remembered that the prisoner, though he had the apparatus all right, had only three slides, and that when he was about to cross the cheque prisoner said, "Don't cross it," and explained that he could pass it on to pay for the cards he required. In cross-examination he said that he had received a letter from the prisoner's wife about Christmas, and one from the prisoner from Devizes goal, about the middle of January.—P.S. Pike, of Blandford, said that he had known the prisoner just over two years. He went to the prisoner's house on October 3. It was a small cottage, and there was a small studio. There were a few blank postcards about. He estimated the number at about twenty. There was a small dark room, and about three dozen printing frames stacked up, but none in use. The household consisted of his wife and two small children, and two females, one of whom was engaged, he found, as a domestic servant. He found a duplicate receipt book, which showed that the prisoner had received orders for about 50,000 postcards, and had received £113 1s. 3d. He did not think from the appearance of the place that the prisoner had space enough to execute the orders.—The prisoner, on oath, made a long statement to the effect that he had been in business at Blandford at three different addresses. Finding he was not doing much business, owing to not being very well-known, he took up outdoor photography, and travelled for orders. He had visited a number of towns in Dorset, and taken orders. He narrated the attempts he had made to get the postcards for printing from different firms, and the prices quoted by London firms. He produced a number of letters from various firms from whom he had been receiving cards, but explained that he had been unable to get postcards in the quantity he required in the time he agreed with the firms to send them. He also stated that when arrested for a charge at Stroud he had an assistant, who, though she had only been with him a short time, had picked up a great deal about the printing of the cards, and his wife assisted with them. During September he had turned out 10,422 postcards, and was in a position to turn out more than that. He had sixty-three printing frames, and could turn out 3,000 cards per day, and had turned out cards at the rate of 2,000 per day. During ten weeks he took orders for 50,000 postcards. He had been arrested for something he had done at Stroud, and had been induced to plead guilty, and throw himself on the mercy of the Bench, and he had consequently been in prison, or the orders of Mr. Hurd and others would have been executed before. He was arrested before the time that Mr. Hurd's proofs were due. His assistant was taken back to Stroud

by the police, or went back, and left his wife, or the work would still have gone on, as he had intended and arranged it should.—Prisoner was committed for trial at the next Quarter Sessions, and in reply to his request for bail to be given a chance to execute these and other orders, the Bench decided to admit him to bail on his own recognisance of £20, and two sureties to be approved by the police in £10 each.

#### HOW THE CANVASSING BUSINESS IS WORKED.

THE conclusion of a case which has been twice adjourned, came before the Cambridge Borough Police Court last week. The previous hearing was reported in our issue of December 22 last, from which it will be remembered that a young man, by name James McBirnie, an agent, in the employ of the Crown Art Company, who lived at 1A, Hertset Road, Seven Sisters Road, London, was charged with having embezzled certain sums to the extent of £1 9s. 6d., the moneys of Alfred Margand, a photographer, who traded as the Crown Art Company. At the previous hearing the prosecutor did not appear, and the solicitor who appeared for the prisoner made certain allegations against the prosecutor, and the case was dismissed. A further charge was taken out, and the case was several times brought before the magistrates, but either the prosecutor or the prisoner did not appear, and it was adjourned until Tuesday, when the majority of the magistrates gave their decision in favour of the prisoner.

In opening the case, the prosecuting solicitor explained that the prisoner was employed by the prosecutor as a canvasser and collector, and that he did business in Cambridge. The prisoner's duty was to canvass people for orders. When he got the order he entered a record on a card with the amount the people who gave the order had paid towards the debt they had incurred. It was further his duty to send to the prosecutor a sheet containing the payments made. When the prosecutor examined these sheets he found that several payments had not been entered. They had prisoner's entry upon the cards showing the amount received in several cases, initialled by himself, and they further had the daily sheets from which these payments were omitted. The whole charge was based on documentary evidence furnished by the prisoner himself, and the evidence of the people who paid the money.

Alfred Margand, 115, Seven Sisters Road, London, bore out his solicitor's statements, and stated that on a card produced there was a sum of 4s. not entered in the sheet of accounts produced. Prisoner had never accounted for the 4s. On other cards there were sums of 6d., 2s. 6d., 2s., and various other items which had never been accounted for. Whilst prisoner was in Cambridge he lodged with a Mrs. Bass. She gave witness some numbers of cards and a postcard, but witness had never received the money tallying with the amounts on the cards. The postcard was read by the prosecuting solicitor, and it directed the landlady to collect certain sums with which to pay her debt. The daily reports which prisoner sent to prosecutor contained several entries of sums for the hire of a porter, but in that business a porter was not required. Another entry was "carriage on goods" 3s. Witness had himself paid that sum at the station when he was in the town.

After a number of women had given evidence as to payments made to the prisoner, Mrs. Alice Bass, of 51, Norwich Street, said that the prisoner had lodged with her for some time, and when he left he owed her some rent. Witness was shown the postcard, and she stated that she acted upon the instructions given, but after her debt was paid she told the people to send the money to the head office.

Jack Bass, 14, son of the last witness, stated that he collected sums up to 9s. for the prisoner, and was paid 4d. in the 1s. commission. The prosecutor was recalled, and stated that the prisoner's wage was 35s. a week, which he received every Saturday.

At this point the magistrates retired, and on their return, the prisoner elected to be dealt with summarily and pleaded not guilty. He said that he was not a canvasser, as the canvassing was done by a number of young ladies, and he followed them and submitted proofs to the customers. After the proof had been passed it was returned to London. He also collected money from the customers, to whom he gave a receipt. In placing the money to the credit of the customers that were at times mistakes. He admitted receiving all the amounts from the customers who had appeared as witnesses. The

reason he left Mrs. Bass's house was because he was recalled to London by telegram, and when he arrived he found there was work for him. As he could not return at once he sent the postcard to Mrs. Bass's son to collect the money in order to discharge his debt to Mrs. Bass. No mention of these shortages was made at the time, and he knew no more.

Miss Ethel Hughes, of 307, Camden Road, gave evidence on behalf of the prisoner. She stated that she was now employed by the People's Art Company, but was formerly a bookkeeper in the employ of the Crown Art Company, whilst the prisoner was working in Cambridge. Her evidence supported the prisoner's statement that mistakes occurred in the crediting of amounts received by all the collectors.

The magistrates again retired, and on returning the Chairman said that the majority of the magistrates thought the prisoner should have the benefit of the doubt which existed, and he was then discharged.

## Photo-Mechanical Notes.

### Some of the Less Known Properties of Bichromated Gelatine.

IN a lecture recently delivered at the London County Council School of Photo-engraving and Lithography, on "The Use of Bichromate Salts in Photography," Mr. E. W. Foxall alluded to some points in connection with bichromated gelatine that are not very generally known to some. One was that although the bichromate of potash renders gelatine insoluble on exposure to light, also spontaneously by long keeping, the bichromate was actually more soluble in a solution of the bichromate than it was in plain water of a similar temperature. For example, in very hot weather, in sensitising carbon tissue, unless the bichromate solution was cooled artificially, the gelatinous coating would run or partially dissolve, or perhaps drain off the paper when hung up to dry, but with plain water the coating would not be disturbed. He also mentions that in the manufacture of carbon tissue in hot weather there was a great difficulty in getting the pigmented coating to set when it was made in the sensitive condition—that is, containing the bichromate salt—than when it is made in the insensitive state. During the lecture he explained that the so-called "continuing" action of light was due entirely to moisture in the tissue, and that it could be very greatly accelerated by increasing the temperature. In illustration of this, a series of examples was shown. In one set the prints had received one-half the proper exposure. One was developed immediately afterwards, and others were kept for different periods in an atmosphere saturated with moisture at a temperature of 85 Fahr. At the end of an hour one of these was developed, and it proved to be too dark as if it had been over-printed; the others were all very much too dark. Another set had been given one-fourth the proper exposure, and kept under similar conditions. That kept for half-an-hour proved to be nearly dark enough; that for an hour just right; the others for longer periods proved to be much over done. In another set the exposure had been reduced one-sixth the normal, and it was seen that after an hour and a half keeping the print was nearly dark enough, and with three hours by far too dark. It was noteworthy with this series, even with the darkest, that the lights were hard, thus showing that the exposure in the printing frame had been too short. He set up an action through the densest portions in the negative. In all the other series shown, the gradation from the highlights for the deepest shadows were as perfect as if the prints had received their full exposure in the printing frame. Another series were treated differently. They received one-half the proper exposure and then made thoroughly dry in a dry closet. They were then sealed up in a metal case and kept for different times—fifty days, one hundred days, and six months.

—and there was no difference between any of them, and the one that was developed directly it was taken from the printing frame. This shows that without moisture there is no continuing action whatever.

### Wet Collodion Problems.

The following series of questions, addressed to us by a reader in Milwaukee, Wis., U.S.A., are not all of them susceptible of a direct answer. We would ask our querist to accept the information as the experience of a practised worker in the wet collodion process:—

1. What is the chemical salt forming the image on a plate that has been treated in the following manner? A plate is exposed, developed, and fixed as usual, intensified with copper and silver, and then treated with a solution of iodine and iodide of potash in water. This changes the image into a bright yellow colour, apparently iodide of silver. We will call this "Plate A." If a piece of zinc be placed on this moist plate it will form a black deposit, apparently reducing the silver haloid to a metallic state, and also forming iodide of zinc. If another plate—what we will call Plate B—be exposed, developed, and washed (without having the unaltered iodide of silver dissolved with a solution of cyanide of potash, or, in other words, fixed), a piece of zinc be applied to it, as with Plate A, no reduction of silver will take place. This leads me to think that there must be a difference (otherwise than quantity) in the iodide of silver on these two plates. Now, on Plate A, is there a sub-iodide present with the regular iodide of silver? If so, what proportion does it bear to the other? Are the two kinds intimately mixed, or does the sub-iodide lie on the surface?

2. What is the chemical action on Plate A of a combined cutting or reducing solution made by adding to a solution of iodine and iodide of potash in water, enough of a solution of cyanide of potash to just discharge the red colour and turn it clear?

3. It has been said that by varying the quantities of the constituents of a combined cutting solution, described in Question 2, that a solution can be obtained which will cut or open the high-light dots in a half-tone negative faster than the shadow dots are reduced, thus decreasing contrast, and that by mixing the solution in a different manner, a liquid is made that will hold the high-light dots (without opening or cutting them, or causing them to become any larger), and at the same time will reduce the shadow dots, thus increasing contrast. Can you tell me how this action takes place, and what proportions to use in making up the solutions?

4. What action would pyrogallie acid, in conjunction with cyanide of potash, have upon Plate A? I have been told that such a solution would both cut (or reduce) and intensify at the same time.

5. What contaminating salt is it (other than carbonate of potash) that is present with cyanide of potash, and causes it to have a dissolving action upon the silver image of a wet plate during the process of fixation? I had it occur with several samples of potash, though I used the solutions very weak and washed the plate thoroughly as soon as it was fixed.

6. How does diffraction affect the high-light dots in a half-tone negative? I understand its action upon the shadow dots, and have read U. Ray's article in a recent year-book, but am still unable to understand its action on the high-lights.

7. Which gives the finer silver deposit, or grains, in collodion? A mixture of iodides and bromide, or a combination of iodide and chloride? In what other manner, if any, do these two mixtures differ?

8. Is there any other way besides the following of removing the iodide of silver from the combination of iodo-nitrate of silver in an old silver bath?

Dilution with water.

Fusion.

Addition of muriatic acid and cyanide of potash.

9. What action does cyanide of potash or cyanide of silver have upon a silver bath? If any, does the acidity or neutrality of the bath affect such action?

— HALF-TONE.

[1. We cannot say if there is present, under any circumstances, a sub-iodide with a normal iodide of silver. If we could tell you this we should have had the long-veiled question of the latent image. If anyone has isolated any of it, it may be difficult to settle the proportion it bears to the iodide in a wet plate.

2. The chemical action on the plate is that the iodine changes metallic silver into iodide of silver, which the cyanide rapidly dissolves.

3. We know this statement has been made, but, in our experience, entirely without foundation. That is a thing that could easily be determined by experiment. Why do not you make a negative and cut it up, so that you can try certain portions of it with solutions, and see if the high-light dots are reduced more or less according to the varying proportions of the constituents in solution?

5. I have never heard of any contaminating salt causing the cyanide to dissolve the silver image. It will do this without any contaminating salt easily with some samples of collodion much more than others. It is probably due to the fineness of the deposit of the silver in your case.

6. As far as we understand, diffraction affects the high-light dots very little indeed if they are built up with the use of a very big stop; otherwise diffraction has exactly the same effect on the high-light dots as it has on the shadow dots.

7. It is probable that the iodide and chloride give a finer grain. Chloride is extremely slow, and therefore in practice is not used, except calcium chloride, which is used as much as anything, because of its deliquescent properties, which are supposed to assist in keeping the film moist.

8. It is possible that there is one way, not mentioned by you, of removing the surplus iodide of silver from a silver bath, and that is simple decantation. If the bath is allowed to stand long enough much of the iodide may settle to the bottom. It must be remembered there must be a certain proportion of iodide in the bath before it can be used in sensitising plates. We have never heard of any other way of getting rid of it other than the ways mentioned; surely these are simple enough.

9. Cyanide of potash is sometimes used to clear the bath that is working slightly irregularly. If the carbonate usually contained in cyanide is present, then it would appear to do this by removing the excess of acid. As soon as it is added it forms a quite flocculent precipitate, which has to be filtered, and this may act as a sort of clarifying agent. It is frequently resorted to for clearing a bath, though we have never heard any definite explanation of the action offered.]

### Albumen Half-tones on Zinc.

In the current number of the "Photographische Korrespondenz" L. Tschörner points out that in Austria the albumen process is most generally used for half-tone block making. The actual formula used being:—

Water .....	60 ccs.
Ammonium bichromate .....	3 grammes.
Alcohol .....	9 ccs.
Ammonia .....	q.s.

Enough of the ammonia being used to give a distinct yellow colour. This is mixed in equal parts with fresh albumen, and then the mixture diluted with an equal bulk of water. This is flowed over the zinc, the plate whirled, dried, and exposed, and then inked up. Tschörner lays great stress on the quality of the ink, and states that in the Vienna school the following mixture has been successfully used for some time:—

Asphalt .....	10 grammes.
Melt by heat and add:—	
Yellow wax .....	16 grammes.
Venice turpentine .....	6 grammes.
Stiff illustration ink .....	40 grammes.

When mixed, the whole is poured on to a stone and well worked up with a muller. This gives very thin, smooth, and resistant films, which develop easily. After developing and drying, the plate is dusted with asphalt powder, and this melted. The result is a ground which will not only stand etching well, but also enables one to do retouching with litho-chalk.

THE Derby Photographic Society, among other good practices, has one of producing a wall calendar embellished with some choice examples of the work of one of its members. The present year's production bears an excellent photograph by G. A. Fowkes, and on the back of the calendar are the fixture list and other club notices. We believe the idea is one which could be imitated by societies as a means of local advertisement.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes."*

The following applications for Patents were made between January 29 to February 3:—

**CAMERAS.**—No. 2,300. Improvements in photographic cameras. John Boulton Brooks, 24, Temple Row, Birmingham.

**PAPERS.**—No. 2,609. An improved process for making photographic papers. Ignaz Hoffsummer, 6, Lord Street, Liverpool.

**SHUTTERS.**—No. 2,713. Improvements in photographic shutters. Gustav Dietz, Birkbeck Bank Chambers, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**BROMIDE PRINTER.**—No. 24,964, 1905. The apparatus consists of a box (containing the illuminant), in which are two apertures—one (d) semi-circular, and the other (e) rectangular, and covered with a ruby glass or other light filter. Above these apertures is mounted a circular board, carrying a pair of printing frames. The printer can work with one or both frames, in the latter

case filling one frame while the other is being exposed. In each instance the exposure is made by turning the circular board and thus bringing the printing frame over the semi-circular aperture. Edward Schneider, 92/2, Tölzerstrasse, Munich, Germany.

**FILM-DEVELOPING MACHINE.**—No. 16,218, 1905. The invention provides a portable reel or spool, the end flanges of which are light-tight but admit liquid. The film is wound on this reel, so that liquid has free access to all its parts, the transference of the film to the reel being made without a dark room. Figure 1 shows this reel empty. In Figure 2 it is seen with the film wound

Fig. 1.

upon it by means of a flexible apron, having a corrugated strip along each edge, in order to keep the surface of the film freely,

exposed to the developing and other liquids. The film is wound on to the apron, as in other machines, for development, and is then removed bodily from the winding box and immersed in the

Fig. 2.

developing tank seen in Fig. 2. Frederick Wayne Barnes, 925, St. Paul Street, Rochester, U.S.A.

**DEVELOPING APPARATUS.**—No. 7,319, 1905. The claim is for the system, and apparatus thereof, of transferring the dark slide containing an exposed plate to a light-tight receptacle, and there admitting developer to the plate as it remains in the slide, other solutions being afterwards applied (after the withdrawal of the previous liquid) for washing and fixing. The apparatus consists of a box or chamber, provided with a slit (closed by a light-tight valve), for the insertion of the dark slide, and a second aperture for the admission of developer. George Edward Hawkes Rawlins, 6, Victoria Road, Waterloo, Liverpool.

**SHUTTERS.**—No. 1,740, 1905. The invention relates to a diaphragmatic ever-set shutter, and includes the following features, for the explanation of which the detailed drawings in the specification must be consulted.

The sectors of the shutter and the driving piece for the sectors are in a casing, made in one piece.

The lens mount is made in one piece, and forms at the same time the cover of the shutter, the diaphragm plates and the driving mechanism being arranged in the cover.

The shutter is made with three sectors or blades. Wilhelm Kengott, 64, Rue de Saintonge, Paris.

**DARK ROOM LAMPS.**—No. 9,661, 1905. The invention is a new type of dark-room lamp, divided into two or more separate com-

Fig. 1.

Fig. 2.

partments, so that these different chambers may be fitted with light filters of different colours. Provision is made for the transference of the source of light from one compartment to another,

and the inventor also includes the fitting of the front of the lamp with glasses at an angle to the front, the latter itself being glazed with a diffusing screen. Instead of transferring the light, two lights may be provided, and turned on and off to illuminate one or other chamber. Fig. 1 shows the construction of the lamp for gas.

The gas supply pipe is fitted with a swing gas joint K, carrying a gas pipe J, and burner U, and lever arm I, fitted in line with pipe J. By moving the arm I, the light is transferred from one part of the lamp to the other. The wings, M and W, are carried on arms, and serve to fill up the opening in the division E made for the passage of the burner. Fig. 2 shows the lamp as constructed for oil. Here the movement of the arm I-J, pivoted at K, causes the passage of the lamp from A to B, and vice versa. There is an arrangement for the lamp to slide on feet or rails from one part to the other. Frederick Thomas Parsons, 27, Southdown Gardens, Wimbledon.

**ELECTRICAL LONG-DISTANCE PHOTOGRAPHY.**—No. 16,796, 1905. The invention consists of apparatus for the electrical transmission of drawings, photographs, etc. The transmitter consists of a rotatable transparent cylinder, carrying the photographic film, and of a box outside the cylinder, having a cell of selenium connected to the live wire above, and a hole below, which latter permits the passage of light from a source of light inside the cylinder. Both the box and the source of light move simultaneously longitudinally to the rotating cylinder. The receiver consists of a rotatable cylinder, carrying a sensitive film, and a mirror galvanometer connected to the live wire, the mirror of which is arranged to oscillate within the galvanometer and spool, and to reflect the light coming through a lateral passage from an outer source of light upon the sensitive film through a minute passage in the bottom plate of the spool, the galvanometer of the outer source of light moving simultaneously longitudinally to the rotating cylinder of the receiver, and synchronising in action with the transmitter. Henri Carboneille, 66, Chaussée de Ruysbroeck, Uccle, Belgium.

## New Books.

"The American Annual of Photography and Photographic Times Almanac." New York: G. Gennert; London: Jonathan Fallowfield. 3s. 6d.

In this twentieth issue of the American Annual, the present editors, W. I. Lincoln Adams and Spencer B. Hord, have gathered much of pictorial and technical interest. The latter portion of the contents is quite above the average, and includes a goodly dose of the experience of practical men. Articles such as those on "Indexing Negatives," "Sporting Photography," "Photographing Children," "Cameo Relief Printing," may not be entirely novel in matter, but they are sound reading such as can be studied with profit by many photographers. The pictorial contents of the book is an incongruous mixture of good and bad. A great many of the illustrations are of the most ordinary kind. Many others which are not ordinary would be all the better if they were. We turn over page after page of reproductions wondering what qualities decided their insertion. One writer titles his theme, "The Mission of Art," and is good enough to say that "professional photographers intent on material reward ignored both fact and truth, turned out insidious things as meaningless as phrases and more misleading than mirage." However, the few photographs in the volume on which it is a pleasure to look a second time are by American professionals. Take away those by Eickemeyer, Strauss, and one or two more, and we are left among monstrosities and eccentricities, the gloom of which is broken only by a few clever pieces of landscape work, such as that of Thomas A. Morgan, Otto Fullgraff, and Jos. R. Igllick. The latter follows the *metier* of George E. Tingley's "Light Beyond," and is quite a relief from the meaningless studies by which it is surrounded. Our readers will find good technical reading worth all the price of the volume, but we hope they will take some of the reproductions at their proper value.

"Martin's Up-to-Date Tables." By Alfred J. Martin. London: T. Fisher Unwin. 2s. 6d.

The author's aim in this compilation is not so much to bring

together a set of tables for reference, but to demonstrate the appalling muddle of our British weights and measures. In saying that he succeeds perfectly in this by no means difficult task, we would not imply that the most elaborate tasks of tabulation are beyond his powers. In fact, his volume is also something of a triumph in attempting to extract order out of the chaos of the English measures. However, Mr. Martin would bring in by gradual and natural means the decimal or metric system, the simplicity and non-ambiguity of which he demonstrates by example after example. Among other suggestions for familiarizing the public with the metric system is the holding of a metric exhibition, where goods shall be bought and sold in metric measures, carpenters work by metre, and grocers' by kilogramme. We look forward to a Metric Earl's Court. However, to describe Mr. Martin's volume as nothing but a disguised argument for the gramme and cubic centimetre would not be to do it justice. It contains a large number of tables which have no mission other than to save the reader time and calculation.

"*Traité Complémentaire de Photographie Pratique*," by G. H. Niewenglowski. Paris: Garnier Freres. Price 3fr.

This work is an advanced handbook and supplementary to the elementary treatise by the same author which was published last year. Practical details are given for pinhole work, and the latest views on the subject and method of finding the amount of subject included are given. The anachromatic lenses of Puyo and Pulligny are described and figured. The carbon process, and its modifications, such as gum bichromate, the powder process, enamels, and photo-reliefs are then treated of. The various processes of making transparencies are described. Panoramic and stereoscopic photography, lantern work, and enlarging also are dealt with, and the final chapter describes the various direct and indirect processes of colour photography. The information given is thoroughly up to date, and the book will form a reliable text-book to the more advanced worker. A collection of formulæ at the end of the work will also add to its usefulness.

"Telephotography for Beginners." (No. 29 of "The Practical Photographer.") London: Hodder and Stoughton. 1s. 3d.

This book begins with an "Easy Introduction to Telephotography," by the Editor, who describes a number of simple experiments in illustration of his subject, "A Cantab" then deals with "Telephoto Calculations by Simple Arithmetic," and various writers contribute useful notes on focussing, exposure, etc. Some good examples of telephoto work are given, and perhaps the most interesting specimen is one of the Barton airship, taken during its trial (and only) trip with a folding pocket camera and Junior Adon lens. A rather brief historical note on telephoto lenses is included, and would have been more complete if it had mentioned the now forgotten "Orthoscopic lens" of Voigtlander, which was certainly of a "telephoto" form, and the recently introduced non-adjustable varieties of telephoto lenses. The so-called telephoto supplementary lenses seem also to have escaped notice. The book should be a distinctly useful one to the "beginners," for whom it is written, though perhaps some of the matter would be clearer if more condensed. It is interesting to note that "A Cantab" falls foul of the photographic habit of calling convex lenses positive and concave lenses negative. He falls in with the practice under protest, but we are not all disposed to believe that it is a purely photographic practice. Oculists certainly adopt it, and the academic convention that makes convex lenses negative and concave lenses positive is strongly objected to by many optical experts on account of its irrational nature and of the many blunders that it leads to.

The critical review is devoted to the work of Mr. A. H. Blake, and is illustrated by eight of his pictures.

The Editor announces "important developments and new features" in forthcoming numbers, so it is evident that the "Practical Photographer" is moving with the times.

**Jahrbuch Dresdner Gesellschaft zur Förderung der Amateur Photographie.**—This annual is practically the report of the above society, but, besides having a list of members and the business report, a number of readable articles are given, and also some good half-tone illustrations. The articles include such subjects as colour photography, halation, stereoscopy, pictorial work and copyright.

A TRANSLATION of the French work by René d'Helicourt has been issued by Messrs. Iliffe and Sons, Ltd., under the title, "Photographic Enamels." It deals with the production of ceramic photographs by the direct powder process and by the substitution methods. The details of firing and retouching are also considered. The volume runs to ninety pages, and is published at half-a-crown.

## New Materials.

Yvonnettes (Silk eye-lashes). Made and sold by Mdme. Catherine Devrient, 20, Abbey Gardens, Abbey Road, N.W.

A novel aid to the photographer in his meritorious endeavours to supply his feminine sitters with charms which Nature may have denied to them has been brought to our notice in the shape of artificial silk eye-lashes, called "Yvonnettes" by their maker, whose own use of them has been proved in the course of a career on the musical stage. The eye-lash is mounted on a narrow silk rim, prepared on its concave side with adhesive, so that when slightly moistened and pressed on the eye-lid it adheres firmly. The rims are made in a variety of tints suitable for blondes and brunettes, supporting, in each case, a black lash. Madame Devrient has demonstrated to us the justice of the epithet "most becoming," which she applies to them, and has induced us to draw the attention of photographers to them in the belief that they will be found a convenient and cleanly device for remedying deficiencies of nature by other means than those of the retoucher. The "Yvonnettes" are sold in sets of four at 1s. 1d.

A HANDY swivel print trimmer for cutting circles and ovals has been introduced by Messrs. H. and W. Green, Crown Photographic Works, Rotherham, at the popular price of 1s. Zinc shapes are supplied to fit all this firm's oval and circle mounts.

## CATALOGUES AND TRADE NOTICES.

A MOST comprehensive list of photographic requisites reaches us from Messrs. Babajee, Sakham and Co., Esuf Buildings, Bombay, a firm which occupies in India a position of supplier of everything photographic, such as that held here by a few leading houses. The list is a bulky volume of 400 pages.

THE February list of new cinematograph films reaches us from Messrs. L. Gaumont and Co., 22-27, Cecil Court, London, W.C.

A NEW descriptive booklet of the "Swincam" tripod, to which we were able to accord a favourable review some months ago, has been issued by the maker, Mr. W. Butler, 20, Crosby Road, Birkdale, Southport. It illustrates the very wide range of movements of which the "Swincam" is capable.

MESSRS. MARION send us a new booklet of the "Soho" Reflex camera, a new size of which—postcard,  $5\frac{1}{2}$  by  $3\frac{1}{2}$ —they have now ready. The booklet illustrates the use of the camera on the football field for Press purposes in a convincing way.

THE Late H. C. Stearn.—We regret to announce the death, on February 9, of Mr. Harry Cotterell Stearn, a partner of the photographic firm of "Stearn, Cambridge." The deceased never really recovered from an illness which seized him last summer. Mr. Stearn, who was himself a keen sportsman, and fond of shooting, fishing, rowing, billiards, etc., died at the early age of forty-seven, and will be much missed at Putney, Queen's, and other 'Varsity rendezvous.

A REQUEST has been made to the National Photographic Record Association by the late Mr. Robert Pearson Brereton, M.A., who left estate to the value of £19,000 on his recent decease. Under his will the N.P.R.A. acquires all his photographic negatives of churches, and details of ecclesiastical architecture. The late donor was not a member of the Association, and his name was even unknown to the officers until the fact of the bequest was made known to them.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.

22.....	Bowes Pk. and Dis. Ph. Soc. ....	Second Annual Exhibition. Members only.
22.....		Annual Exhibition.

### ROYAL PHOTOGRAPHIC SOCIETY.

ANNUAL meeting held Tuesday, February 13, Major-General Waterhouse, I.A., in the chair. The report of the Council was submitted for discussion. From the report it is seen that the finances of the Society are in a distinctly more satisfactory state than they were a year ago. Increased expenses have been met by the recovery of subscriptions in arrears to the amount of £160. A large number of

members in arrears with subscriptions for two years and upwards had been struck off the roll, making a net decrease of ten in the actual efficient membership.

The application to the Society by the local rating authority for payment of £70 per year rates had been successfully resisted, and it was announced that the Society would be exempt for, at any rate, five years.

In the discussion on the report Mr. Casson suggested that wall space at the exhibition should be charged for to non-members. He thought it anomalous that so few photographs at the annual exhibition should be by members, and he thought that if preference were shown to members in regard to the exhibition charges, the effect would be that many exhibitors who were not members would join the Society.

Mr. J. C. S. Mummery pointed out that the question had been carefully considered by the Council, and the Secretary stated that forty new members had been added to the Society from the last exhibition.

In regard to the forthcoming issue of a catalogue of the Society's library it was announced that a charge will be made for it.

The report announces the abandonment of the scheme of a photographic research laboratory, for the support of which the total promised amounts to only £136. Major-General Waterhouse said in response to a question by Mr. A. Mackie that the Council could not be said to have fairly considered the question, which at a subsequent stage had been submitted to him, and in regard to which he had concluded that the building, from its position among heavy traffic, was not suited to research work; and further, that the cost of a proper equipment and upkeep involved the subscription of a large sum of money.

In regard to a question by Mr. R. Child Bayley on the Affiliation, the Secretary stated that a new financial arrangement had been come to under which the R.P.S. provided the Affiliation with house-room, two or three pages each month in "The Photographic Journal" for reports of its proceedings, and with a copy of "The Photographic Journal" for each Society. The Affiliation receives its own revenues and meets its other expenses.

The report of the scrutineers of the ballot was received and approved. The following were found to be the officers elected for the current year.

*President.*

Major-General Waterhouse, I.A.

*Vice-presidents.*

Sir W. de W. Abney, K.C.B., D.C.L., F.R.S.  
The Right Hon. the Earl of Crawford, K.T., F.R.S.  
J. C. S. Mummery, A.R.I.B.A.  
Sir J. W. Swan, F.R.S.

*Treasurer.*

John Sterry.

*Council.*

A. W. W. Bartlett.	Furley Lewis.
I. W. Bennett.	Ernest Marriage.
Leslie E. Clift.	Prof. R. Meldola, F.R.S.
Douglas English, B.A.	F. J. Mortimer.
E. Freshwater, F.R.M.S.	C. H. Oakden.
John H. Gear.	E. Sanger Shepherd.
Sir W. J. Herschel.	C. Winthrop Somerville.
Red Hollier.	J. Spiller.
Lindsay Johnson, M.A., M.D.,	H. Snowden Ward.
B.Sc., F.R.C.S.	B. Gay Wilkinson.
Rev. F. C. Lambert, M.A.	

The following were elected judges in the technical section at the forthcoming exhibition. The selection committee in the pictorial section is appointed by the Council:—

Thomas Bolas, F.I.C., F.C.S.	Sir J. W. Swan, D.Sc., M.A.,
Douglas English, B.A.	F.R.S.
Chapman Jones, F.I.C., F.C.S.	Major-General Waterhouse, I.A.
Sanger Shepherd.	

## THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, W., on Friday, February 9. Present: Messrs. F. A. Bridge, Alfred Ellis, E. C. Elliott, S. H. Fry, Wm. Grove, H. E. Hull, Martin Jacquette, Alex. Mackie, H. S. Mendelssohn, D. Prodder, E. Scamell, Lang Sims, P. Lankester (Tunbridge Wells), and H. C. Spink (Brighton). In the absence of the President, Mr. Alfred Ellis, Past President, took the chair.

The meeting was devoted to making arrangements regarding the Annual General Meeting to be held on Friday, March 9. No other matters of detail.

**THE BRISTOL PHOTOGRAPHIC CLUB.**—On Tuesday in last week at Headquarters, 5, St. James' Square, Mr. Easonsmith gave a lantern lecture entitled "The Camera as a Diary." The lecturer pleaded for the consideration of this aspect of a camera, apart from its use for pictorial or scientific purposes, and justified his plea by the fact that it enabled one to re-enjoy many happy hours from the past.

**CROYDON CAMERA CLUB.**—A very pleasant evening was spent on the 7th inst., listening to a chat about photomicrography, by Mr. Bawcomb, his observations being illustrated by a series of most interesting slides. The lecturer frankly confessed he had taken up the subject simply for amusement and instruction, and with no thoughts of specialisation; he thought if others would do the same they would never regret it. Photomicrography presented no special difficulties unless high magnifications were attempted, but these were not often necessary. Although he possessed a battery of objectives up to one-twelfth of an inch, yet he had found 3 to 1 inch most useful. Focussing was best performed by observing the aerial image through an achromatic magnifier, a piece of plate glass with scratched cross lines, being substituted for the more usual ground-glass screen. The introduction of Gordon's apparatus, as made by Messrs. R. and J. Beck, had simplified the process considerably. This consisted essentially of a tube having at its upper end a small dry plate in a light-tight chamber, and lower down a projection lens focussed upon the plate, together with a simple form of exposing shutter. The lower end was adapted to make a light-tight join with the eye-piece of the microscope. Generally speaking the photograph would be sharp, when the microscope was in focus, but any error that might occur through variation in vision was remedied by using a supplementary tube, containing an eyepiece of high power, to focus by, this being removed before exposure.

In the discussion which followed Mr. Packham agreed with the lecturer that excellent work might be done by beginners if they confined themselves to low powers, nor was such elaborate apparatus essential, as Mr. Bawcomb was the happy possessor of. Mr. Kenneth Mees pointed out in reference to high magnifications, that far greater resolving powers were obtainable, by the use of purely monochromatic light in the violet, or even the invisible ultra-violet end of the spectrum. There was then no necessity to employ achromatic objectives.

**ABERDEEN PHOTO-ART CLUB.**—At a meeting of the Club last week, Mr. J. A. H. Hector, of the School of Design, delivered a lecture on "The Principles of Artistic Selection." By artistic selection he intended to refer to the selection of the treatment of the subject and the personal elements and individual feeling brought into play in the doing of it. Every subject required close watching to find out some quality which would embody an idea that would appeal not to the eye only, but to the mind. Showing a picture of Scottish mountain scenery, in the mists of winter, the artist said that this same scene in summer would have been uninteresting. It needed the selective faculty to wait for those mists, with the wild light on them, creeping through the glen, blotting out detail and giving a suggestion only of mountains beyond, to give a feeling of grandeur and greatness to the scene. The lecturer dwelt at some length on the quality known as "tone." Between the extremes of black and white there was a great range of tones, and the greatness of an artist depended on his treatment of these. The fineness of gradation in these tones determined the success of a picture. He did not mean that one tone should merge into another with mathematical precision. Often the missing of several tones in the range of gradation gave that feeling of surprise which we knew as variety in a

picture. With a number of slides and pictures Mr. Hector showed what he meant by the selection of treatment. By simply drawing a slide, full of microscopic detail, slightly out of focus, he showed the pictorial possibilities that lay in the commonplace when subjected to selective treatment.

**SOUTHAMPTON CAMERA CLUB.**—Mr. J. W. Eadie lectured to the members of the above on Monday evening, the 12th inst., his subject being "Pictorial Possibilities," and, while his particular object was the demonstration of Kodak apparatus to this end, his lecture was full of practical advice. Dealing with processes, Mr. Eadie pointed out that while different methods of developing and printing produced varied effects in the completed work, the idea sought to be conveyed by the picture should be attained in the composition before exposure was made. Dealing with the difficulties to the pictorial worker of the stereoscopic effect of ordinary vision and the flat effect of the ground glass inverted image in focussing, Mr. Eadie advised the members to do their composition with one eye closed, so as to see things as the lens sees them, and pointed out how the window of a moving railway carriage under such a method furnished a continual succession of composed subjects of extreme interest. The lecturer pleaded for an effort by workers to see every-day subjects in an unorthodox way, to be always seeking the new view of even the most ordinary and commonplace objects. As an instance of what was possible, he mentioned the work of Mr. Coburn, who, coming from America, had given us a wonderful picture of London Bridge totally different from anything done by any of the well-known home workers. The true picture was that which, leaving aside considerations of record, embodied an idea or a sentiment, and the successful picture was that which, though it might be lacking in some technical success, yet carried conviction with it.

## Commercial & Legal Intelligence.

**THEFT of a Camera.**—John Appleby, 31, dealer, was last week found guilty of stealing a camera, the property of the Stereoscopic Company, Cheapside. Mr. Graham Campbell prosecuted, and Mr. L. Green defended. The camera was ordered to be sent to an address, and the prisoner, pretending that the cover was required, sent the boy bringing the camera back for it. When the boy returned the prisoner had disappeared with the camera. The prisoner had twice previously been tried for a similar kind of offence and was acquitted. Detective Crouch had charge of the case, and Detective Hayman said the prisoner had been known to follow as many as twenty boys who had been sent to banks or with parcels in the course of a single day. Many complaints had been received of boys being robbed, but since the prisoner had been arrested these complaints had ceased. The Recorder sentenced the prisoner to twelve months' hard labour, remarking that this plan of robbing boys was a very old trick.

**IMPROPER Postcards.**—Louis Goodman, a foreigner, carrying on business at Broad Street, Golden Square, was summoned at Marlborough Street last week for exhibiting in his shop window a number of improper postcards. Mr. P. Robinson, defending, said that no doubt some of the cards were of an undesirable character, and he was prepared to have them destroyed. It seemed that it would be a good thing if the authorities would prosecute the publishers of these cards, and not keep on summoning those who had little shops. Defendant, when spoken to, said others sold them. Why should not he? Fined £25, with 4s. costs; the cards ordered to be destroyed.

**BANKRUPTCY at Smethwick.**—The first meeting of the creditors of Charles Frederick Norris, photographer, of 95, Cheshire Road, Smethwick, and carrying on business at 139, Dudley Road, was held at Ruskin Chambers on February 8. The debtor's statement of affairs disclosed liabilities amounting to £385 5s. 11d., and no assets. The cases of failure as alleged by bankrupt were "bad trade, illness of wife and family." From the Official Receiver's observations it appeared that bankrupt was engaged as a photographer's assistant until 1887, when he commenced business on his own account at 139, Dudley Road, with capital amounting to £5, which he had saved. In 1900 he opened a branch shop at 95, High Street, Smeth-

wick. He subsequently purchased the property for £350 with money advanced by his bankers, who were secured by the deeds of the property and two policies. The bankrupt traded without difficulty until December, 1903, when he was in arrear with his rent, and the landlord lent him £50. A few months later the bankrupt borrowed £20 from a professional moneylender, and agreed to repay £25. Other transactions followed, and the moneylender is a creditor for £75. Trade had been bad the last two years, and the bankrupt had been caused additional expense with the illness of his wife and a child. In June, 1905, the Smethwick property and the two life policies were sold by his bankers, who received £494. A cash book had not been kept. Mr. Sharp said it was a case of trying to trade with borrowed money and digging one hole to fill another. The case was a summary one.

**CANVASSING Amenities at Colchester.**—A police court, which held up the profession of photography in a very unfavourable light, came before the Colchester magistrates last week. The dramatis personae were:—

Charles Wilfrid Hiscox, a photographer.

Edward A. Smith, previously his canvasser.

It was alleged that Mr. Hiscox was out photographing when Smith called at his house and sent for him, saying he wanted to see him particularly. On his arrival the defendant entered into a dispute with him as to 3s. 9d., alleged to be due to him as commission. He then rushed at Mr. Hiscox, striking him several times, and subsequently in the street pulled him down on the ground and inflicted several blows on his head. A different account of the incident was given by the defendant, but the Bench considered an unprovoked assault had been committed, and fined the defendant 10s., with £1 costs.

**THE "Free Enlargement" in Court.**—At Merthyr County Court last week the London Artistic Photograph Company claimed from William G. Edwards, formerly of Bargoed and now of Cefn, a balance of 17s. in respect of 23s. charged for two frames supplied to the defendant, for whom they had made two gratis enlargements. Mr. W. R. Edmunds appeared for the defendant, whose wife alleged that the charge was to have been only 10s., on account of which 8s. 6d. had been paid. Judgment was given for the plaintiffs.

**ACTRESSES' Photographs.**—Before Mr. Justice Warrington, in the Chancery Division on Friday last, Mr. Waggett said he had a motion for an injunction in an action of Doff Brothers, of Manchester, against Albert Sachs, of Bradford, to prevent the publication and circulation of photographs of certain ladies named Daisy Jerome, Mabel Lait, and Godwynne Earle (who were acting in a pantomime at Bradford) on picture postcards. Mr. Waggett said it was a motion by a pictorial publisher at Manchester against a well-known photographer at Bradford. He understood that his learned friend was willing to give an undertaking with regard to the negatives of the photographs of which plaintiffs complained, which were taken on certain days—namely, that defendant would not sell photographs taken from those negatives until judgment or further order in the action, the photographs being of the three pantomime ladies mentioned. They would then get ready for a speedy trial, and would later on apply for a day to be fixed so that they could get the ladies there in court. —Mr. Cartmell assented, and said the undertaking was given entirely without prejudice to defendant's rights. He considered that he had a complete answer to the case, but he knew the particular negatives of which plaintiffs complained, and he was willing to give an undertaking only as to those negatives.

**A DEBT of £17.**—At the Lord Mayor's Court, on February 9, before Sir Forrest Fulton, K.C., Recorder, and a jury, Major Sawyer, New London Street, E.C., sued Mr. J. W. Meek, 32, Albert Road, Stroud Green, for £17, money lent.—Mr. Davenport (instructed by Mr. Edwards) was counsel for the plaintiffs, and Mr. Hawtin (instructed by Mr. Morros) for the defendant.—The plaintiff said that in August, 1904, the defendant came to him and said the business which he was connected with was in liquidation, and he was able to buy the assets for £17. He (plaintiff) eventually advanced that amount. An option was given to him to enter the business, but it had not been exercised.—The defence was that the plaintiff entered into a joint venture for the purchase of the assets of the Pocket Photography Company. They were to share the profits and divide the expenses between them.—The jury found a verdict for the plaintiff for the amount claimed.

**THEFT by a Photographer.**—At the West Ham Police Court on Friday, George Mole, alias Bunning, 23, a photographer, of 57, Larch Road, Cricklewood, was charged on a warrant with obtaining a bicycle and a camera by false pretences. On March 29, 1905, Arnold Ducker, of Wealdstone, Harrow, answered an advertisement offering a camera for sale, and subsequently rode to 3, Raymond Road, Upton Park, on a bicycle. There he saw the prisoner, and after some conversation, Ducker told him he had a camera which he would sell for £4 10s., and the prisoner said he would go and see it. Ducker mentioned that he would also sell the bicycle, and the prisoner agreed to give him £8 15s. for the two. On April 5, Ducker took the articles to the prisoner's house, but Mole said he had been unable to get the money out of the bank. He showed Ducker round the house, and gave him to understand that he was the son of the landlady, and eventually both the camera and the bicycle were left for him to try. On the date fixed for concluding the sale Ducker received a postcard from the prisoner, who stated that he was going away on business till the following Monday. On that day Ducker went to the house again, but found that the prisoner had gone. Later in the day he found his bicycle at a secondhand shop in Plashet Lane, Upton Park, where the prisoner had sold it two days previously for 18s. The camera was subsequently traced to a pawnbroker's, where a young fellow had pledged it in the name of Joseph Bunning for £1. The prisoner pleaded guilty, and said he had paid as many of his debts as he could. Mr. David Howard (the Chairman) said the Bench had to administer the law. He would go to prison for two months with hard labour.

#### COMPANIES REGISTERED.

**COLOUR, Limited.**—Capital, £100,000 in £1 shares. Object: To adopt an agreement with O. Shore, and to carry on the business of typographic half-tone printing, general printing, lithography, and publishing, etc. The company is expressly prohibited from manufacturing and dealing in photographic plates, films, and paper, or other photographic appliances or supplies, or doing anything in contravention of an agreement between the Eastman Kodak Company, of New Jersey, U.S.A., and J. Cadett, dated July 23, 1903, but only for so long as the said J. Cadett shall be in the service of or a shareholder in this company.

## News and Notes.

**SOUTH LONDON Photographic Society.**—The entry-forms for this society's forthcoming exhibition are now ready, and can be obtained on application to Mr. H. Creighton Beckett, 44, Edith Road, Beckham.

A **DESTRUCTIVE** fire occurred last week at the photographic shop of Mr. William Muntz, Leyland Arcade, Lord Street, Southport. The contents of the premises, including some valuable oil paintings, were destroyed. The damage, which is partly covered by insurance, amounts to about £700.

AN exhibition is to be held at Milan from April to November in celebration of the opening of the new Simplon Tunnel. A photographic section is to be arranged under the direction of Professor Namias.

A **VELOX** supplement, tinted in water colours, is presented with each copy of the current "Camera" (Philadelphia). A very pleasing effect is obtained by what must, necessarily, be an expeditious process.

WE confess some of our American contemporaries are hard reading. Among a number of disconnected paragraphs we note the advice:—Don't be scared because 'smarty' says he wants 'his head struck'; its light and tender."

THE Bristol Photographic Club have decided to hold an exhibition of pictorial photography in the autumn, and the members have already guaranteed an ample amount for carrying the project into effect. It is many years since such an exhibition was held in Bristol, and it is intended to make this one thoroughly representative

of the high position in art now held by pictorial photography. The hon. exhibition secretary is Mr. J. S. Guthrie, 23, Berkeley Square, Bristol.

THE twelfth Chemists' Exhibition will be held at the Royal Horticultural Hall, Westminster, from April 23 to 27. As in previous years, the photographic trade will be represented in the exhibition. All particulars are obtainable from its organisers, "The British and Colonial Druggist," 44-47, Bishopsgate Street Without, E.C.

ULVERSTON, Lancashire, appears to be just now a peculiarly profitable field for the cheap itinerant photographer, a large proportion of whose trading is done on the Sunday. The Urban Council has had its attention called to the congregation of young people in the street waiting their turn to be photographed, and the police have been communicated with to limit the nuisance.

A **FURTHER** sidelight on the undesirables who are to be found in the ranks of the migratory photographers is conveyed in the report of a case which came before the Menai Bridge Sessions last week. Anthony Ansonia, travelling photographer, Bangor, was charged with cruelty to a horse. Mr. Owen Trevor Williams, veterinary surgeon, Llanelwini, described the horse as being "a living skeleton." Further, there was no digestible grass on the small island where the horse was kept. The defendant (sworn) said he himself was away, but received reports twice a week from his son about the horse, from which he gathered that the horse was all right. The Chairman said the Bench had decided to convict, but as the costs were very heavy they would impose a fine of 10s. 6d., to include everything.

"PUNCH" on the Gum Process.—"Dundee has been wondering why so many members of the dental profession have honoured her with a visit during the past week. It is due to a statement in the "Amateur Photographer." In reviewing the exhibition of the Scottish Photographic Salon now being held in that town, our contemporary draws attention to the fact that "the President, G. D. Macdougald, is exhibiting some of his delightful gums, distinguished by that grace and beauty that caused such a furore when he exhibited at the last Salon."

THE Austrian exhibition to be held at Earl's Court at an early date will have photography and photo-engraving, represented by the following exhibitors:—Karl Pitzner, Vienna; J. Löwy, Vienna; Angerer and Goeschl, Vienna; Theodor Schlimpflug, Vienna; J. F. Langhaus, Prague; and the Austrian Photographic Society, Vienna.

AN exhibition of artistic stereoscopic photography is to be held in Vienna from June 20 to the end of August. It is promoted by the journal "Photo-Sport," to the offices of which at Hauptstrasse, 95, Vienna III., enquiries for further information should be made.

AN appreciation (?) of Photographic Art (?).—A correspondent of the "Liverpool Daily Post," who has visited the exhibition of the Liverpool Amateur Photographic Association, has written his impression of one photograph of the impressionist class which so closely accords with our view of what is hailed by some as embodying the highest aims in photography that we find space here for the major portion of it:—While wandering round the room I was startled by a frame containing what appeared to me to be a delineation of a mass of conventional leaves in some colouring medium which was quite unlike anything else I could see, except perhaps in two other examples close by. I looked earnestly at this exhibit, and retired to a distance and spent some minutes hoping to elucidate the mystery of the title, "A Woodland Pool." I gradually evolved a tree trunk and some splashes on uncoloured paper, or canvas, or what not; but no pool. I went near and found that here and there some green colour had found its way—accidentally or by design I do not know—and I then ventured to consult a bystander, who informed me that this was an example of what is called the "oil process." I asked myself whether such a thing should appear as an example of photography in an exhibition from which, in all probability, a large picture in pastel on a foundation of a bromide enlargement would be excluded; yet it would manifestly be easier to reproduce copies of a pastel than of such a thing as this, as much of what might be called work in it is obviously added by brush or finger, or may be accidentally, while the effect produced, to sum up everything, is like nothing in nature.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### FILMS VERSUS PLATES.

To the Editors.

Gentlemen,—While the question of the value of films against plates is before the photographer, I may perhaps intervene, and give some experience with films, a grain of practice being, the old proverb tells us, worth a bushel of theory. *En passant*, I will refer to some of the queries put by "Wet Plate," who initiated the discussion, taking first the last of the three points he raises—the cost. Surely he has access to price-lists. He will find from these that the cost of cut films is little more than half as much again as that of plates the same size, and roll films more than double the price.

"Portability." That question answers itself. Films, either cut or roll are certainly more portable than glass plates. Even with the common or garden magazine hand-cameras and cut films, a dozen glass-plate sheaths are usually replaced by two dozen for films, while roll-films for several dozen quarter-plates, for example, could easily be arranged in a waistcoat pocket.

"Quality of result." Here we are on less certain ground. If the point to be determined is the suitability for producing negatives to be criticised with mathematical accuracy, then films will not be admissible; they would be scarcely desirable, for instance, for astro-photographic work. For everyday work, in the studio or field, using full aperture of the lens, I have never had the slightest cause to complain of any destruction or diminution, even, of definition with films up to half-plate in size. Beyond that size I am unable to speak from personal experience for ordinary camera work. With regard to spools of films, I suppose I have developed some thousands for amateurs, and, excepting where there has been obvious disarrangement (usually through carelessness) of the film from its proper position, I cannot charge my memory with any lack of sharpness through the film not being true to focus.

In placing cut films in the dark slides I have never found it necessary to study portability, and the plan I have adopted is simplicity itself. I first put in the film, and then, on the top of it, place a glass plate or an old negative. Working at *f*/3.5 in the studio the results were indistinguishable from glass negatives for all practical purposes. But where portability and light weight is essential "Wet Plate" can purchase cut films enclosed in special carriers without extra cost, or, if he wish to be able to use any film on the market, there are numbers of inexpensive kinds which answer admirably.

One correspondent says, if prints are wanted the films "can be varnished with water varnish; spirit will not do"; but I may tell him this is quite a mistake. I have varnished a large number with the ordinary spirit varnish, dried off with list. The method to adopt is to have the varnish in a wide-mouthed bottle, and lay it on with a wide camel-hair brush, one similar to an ordinary copying-book brush, but of better quality than they are usually made. There need be no fear of streaks or spots if the varnishing be quickly and carefully done. If wanted often, the brush may be left in the varnish, and a suitable cover made to prevent evaporation. If only occasionally required, the brush may, after squeezing out all the varnish possible, be quickly cleaned by well working a few drops of strong ammonia solution into the hairs, and then washing under the tap; the ammonia, as I long ago discovered, renders the varnish miscible with water without being precipitated.

A very interesting aspect of the case, and one which I have been intending for some time to bring before the notice of the readers of this journal, is the keeping quality of the plates. Celluloid as a base for gelatino-bromide films has not the best of reputations; but there are films and films. I once placed two dozen films, by a popular maker and not a year old, in a magazine hand-camera, and exposed all of them one afternoon. The results were simply detestable—spots, fog, and almost every ill a plate could suffer from.

Some little time ago I came across several dozens of 12 x 10 and 15 x 12 films that some of my assistants had carefully put where no one could see them, and they had been lost sight and count of for many years. More out of curiosity than anything I determined to see what they were like when exposed and developed. To my surprise and pleasure they were as good as on the day I received them from the makers, though I was under the impression that I had received these particular films prior to some I had been using in the early days of the Röntgen-ray work (films are very useful and free from liability to breakage in skiagraphing). Having no use at the time for films of that size, I cut up the whole number—several dozens—into half-plate size, and every piece developed into a perfect negative. More remarkable still, some of these films were orthochromatic, which of itself would usually be considered condemnatory of either film or plate, when of considerable age. There was another remarkable peculiarity about them. Whether from extra care in packing, or because they lay so close together, there was an almost complete absence of that well-known iridescence at the edges of the film that is almost invariably seen in glass plates as usually packed. From the date I mention, it will be seen that these films were by some of the earliest makers in the field—Edwards and Thomas respectively. I was so impressed by the importance of these results that I wrote to the makers giving the batch numbers from the packages, and asking if they could tell me the date upon which I had them. The replies were to the effect that batch dates were not preserved for longer than ten years; but that they should think that the films were about fifteen years old. I do not hold a brief for cut-film makers, but I think I have made out a good case for them.—Yours faithfully,

G. WATMOUGH WEBSTER.

1, Grange Road, West Kirby.

### A PHOTOGRAPHER IN RUSSIA.

To the Editors.

Gentlemen,—I think that, perhaps, the following extracts from a letter I have just received from a friend of mine who is an ardent amateur photographer, and lives in Moscow, may not be without interest to your readers:—

"You must know that for over six weeks no mail (private) was delivered in Moscow; of course you have read all about the troubles.

"What times we have had here; I thought many times how interested you would have been if you had been here. The first day of the disturbances I met with a little excitement at the corner of the Tverskaia and boulevard opposite the Monastery. I stood on the corner when the mounted soldiers from the Governor's house swept past, driving people into the side street; reaching the square they took the first street across the square, left-hand side. Soon after they had disappeared shots were heard, and from that time on the times were lively there, believe me.

"Of course, when the firing began I should have made myself scarce, but thought that because I was decently dressed I need not fear.

"I stood, as already stated, on the corner watching all these occurrences with great interest (but no time to load camera, so missed many interesting pictures), when suddenly a whole troop of mounted soldiers rode over to a small group where I was standing and told us to disperse. I like the others, began to look where to shelter, when you can imagine my surprise to see soldiers firing down the boulevard towards the Chief of Police's house. Being on the left side there was not a street to run down, not a gate open, so I was obliged to take to my heels and ran about the distance from the Magasin to Smith Bridge with shots flying on all sides. One or two passed unpleasantly close to my ear; I was in a quandary, and did not know whether to keep on running or lie down flat. I finally reached a doorway at the end of a long (seemed to me interminable) fence, and what a squeezing and scampering trying to force the door! I tried my best to push some one of the six or seven other people between myself and the firing. Finally the door gave way, and we rushed in. Once inside, I turned and looked across the boulevard and saw a number of bodies, perhaps wounded, lying in the snow. I loaded my camera and took a snapshot from the door, and send you a copy. The soldiers are too far away to be very clear, but you may be able to locate the place. After a little rest, I, with a photo-

grapher I know, started to cross the boulevard, on the run, in order to reach a side street, when the soldiers began firing on us, no doubt thinking we were going to the assistance of the men lying in the snow. Anyway, we got safely across, and I made a bee's line for home, having had enough for one day; but I had only commenced with the horror. I live close to the Ekaterineenskie Hospital, and for three hours I stood and saw the wounded shot on and about the Tverskaia brought in all kinds of conveyances to the hospital; the most part were wounded in the thighs and back. Some were killed and wounded whilst assisting the wounded. You have, no doubt, read in the papers more than I can tell you. When the black band, or policemen, were breaking up the barricades the first time I thought they had left our vicinity and went to the gate to have a look at what they had done, when a bullet whistled past our heads (my daughter and self), burying itself in the wooden door jamb. Lively times for people with heart failure!

"It would astonish you to hear how many people died from fright during the revolution here; how many sad tales we hear; innocent children and women killed."—Yours faithfully,

ARTHUR V. KENAH.

Prudential Buildings, Queen Street, Nottingham,  
February 3, 1906.

### COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have now seen your colour exhibition, and I hope you will allow me to point out the following: My prints are intended to show what my invention—made since September, 1905—of a one-exposure camera can do; further improvements to follow.

By the Jumeaux process—the only one of English origin, and known to me before the carbon process—the interposition of celluloid films is not an advantage, especially if the process is used to show pictures print-like, but for ordinary transparencies, which are not required for projection, the Jumeaux process is the easiest method known.

Suppose you receive from an unknown source three negative colour records and an order with them to print 10,000 postcards. With Dr. Jumeaux's process you are in a position to verify easily if the colour records are correct, and what the resulting picture should look like; if you require is two bromide plates for blue and one gelatin-coated film for each other colour.

To show Jumeaux' process to better advantage in the exhibition send herewith two transparencies. The first picture is taken with no screen only (the red sensation). The quasi-instantaneous picture is taken with a Bennetto camera, a system which does not give three pictures of equal size—a defect that all cameras with the now known reflector system have, but which defect is not detrimental when superposition is made with a chromoscope.—Yours faithfully,  
OTTO PFENNINGER.

105, Hythe Road, Brighton, February 10, 1906.

[While not endorsing all our correspondent's statements, we have added the two examples to the exhibition. We refer to the Jumeaux process on another page under "Colour Photography."—Eds., J.P.]

### "THE PHOTOGRAPHIC SOCIETY."

To the Editors.

Gentlemen,—In a county-court case recently, in which a photographic operator sued for a week's salary in lieu of notice, the plaintiff's counsel is reported to have stated that he appeared at the instance of "The Photographic Society," and that the case "affected the whole of the 15,000 members of that Society."

I have made careful inquiries, but, so far, have failed to find anyone who can give me any information about this gigantic organization. Perhaps one of the 15,000 will kindly supply your readers with some particulars. It seems a pity such an apparently important institution should be allowed to follow the example of the modest *plet*.—Yours truly,  
ENQUIRER.  
London, February 10, 1906.

Gentlemen,—In a report of an action brought by an operator for recovery of wages it is stated that the plaintiff was a member of

a photographic society, and the case was of interest to its 15,000 members. The Co-operative Photographic Society beg to say that they are not 15,000 strong. The report should have read that the case was fought by the Society on the ground that it was of interest to 15,000 photographic workpeople.—I am, sir,

p.p. THE CO-OPERATIVE PHOTOGRAPHIC SOCIETY.  
G. PALMER, JUN.

Great Eastern House,  
20, Bishopsgate Street Without, London, E.C.

### THE FREE PORTRAIT SWINDLE IN CORNWALL.

To the Editors.

Gentlemen,—Here is another case of the free portrait swindle. I thought I would test it, as the circulars were sent into this neighbourhood in great numbers. I sent a cabinet photograph, they wanted 8s. for the enlargement without a frame. I got it at last for 5s., and 2s. is all it is worth. And yet there must be many in this country who are being duped.—Yours truly,

A CORNISH PHOTOGRAPHER.

Camborne, February 10, 1906.

[The circular letter is in the customary style of the French free-portrait swindler. It refers to the choice work of art which must be properly packed and forwarded at a cost of 8s.: for which an elegant frame may be purchased at a special discount of 20 per cent. off the list price. This offer is made broadcast in a printed letter. It seems extraordinary that the public can be taken in by such offers, but human gullibility appears to be a quality upon which audacious swindlers cannot assume too much. We hope that residents in the West of England, to whom the gratuitous portrait has been offered, will benefit by the experience of others.—Eds., B.J.P.]

### PHOTOGRAPHING ANTIQUE FURNITURE.

To the Editors.

Gentlemen,—I beg to submit for your inspection a few prints from negatives of inlaid cabinet work, taken on orthochromatic plates ("Spectrum") with the aid of a deep screen ("Absolutus"). The open air is always best for this sort of work, and then the exposures will not be unduly prolonged, from one to three or four minutes being usually sufficient with a moderately small stop.—I beg to remain, Sirs, your very obediently,  
AUG. F. PERREN.

7, Edgar Buildings, Bath,

February 13, 1906.

[The specimens sent by our correspondent comprise very varied descriptions of furniture, including bold Sheraton inlaid work to decoration of a much finer character. The latter especially are excellently reproduced, and we think that such rendering could not be obtained without a screen. In two cases the correction appears to us overdone; a lighter screen or a longer exposure would have been all the better; but the quality of the work as a whole confirms us in our advice of a fortnight ago.—Eds., B.J.P.]

### FLASHLIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—After reading Mr. Corke's letter in your issue of February 9, I am sending you three photographs. They are from a series taken of the Hildenborough Village Players, two years ago. One flash lamp only was used. Exposure, a fraction of a second. Lens used, Zeiss double Protar, stop  $f/8$ . The home of the Village Players is a small iron room, and the area of the stage opening would be about 16 ft. wide by 8 ft. high.

Tonbridge is always looked upon as a bit behind the times, but surely Sevenoaks may now take the bun, especially if one reads your notice in "Ex Cathedra," "Snap Shots in the Studio."—I am, gentlemen, yours faithfully,  
T. A. FLEMONS.

Tonbridge, Kent.

[Mr. Flemons' prints are excellent specimens of flashlight, and we insert the details of their production, although we are at a loss to perceive the relevance of the last paragraph of the letter.—Eds., B.J.P.]

## Answers to Correspondents.

- \* \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- \* \* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \* \* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \* \* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- M. H. Grocock, Laurel Cottage, Ulverston. *Two Photographs of Lady Moyra Cavendish.*
- J. H. Smith, The Studio, Waller Hill, Skipton. *Two Combination Photographs: Skipton and Bolton Abbey.*
- W. M. Rodgers, 57, Murray Place, Stirling. *Two Photographs of the Marquis of Graham.*
- J. A. Beckett, 117, High Street West, Wallsend-on-Tyne. *Two Photographs of the late Mrs. Henderson.*
- J. Hix, The Studio, St. Marychurch. *Photograph of John Kelly, Centenarian.*

**RESIDUES.**—Can you say in your next issue what is the best way to save the silver from P.O.P. washings and fixing solutions? I have added salt as in ordinary silver prints, but it does not settle. I usually place prints in sulpho-gold without previous washing. I wish to save silver from this.—R. D. B.

If fixing baths are mixed with the washes, salt will not throw down the silver. The proper substance is liver of sulphur, which is added and stirred up. If the solution, after settling, gives a precipitate when a little more liver of sulphur is added, the whole of the silver is not down, and, further, "liver" must be added. The gold from the toning bath can be thrown down with sulphate of iron.

**TONING BROMIDES.**—Could you please inform me by what process the — produces the tone that they get on their cards of actresses?—MACK.

By sulphide toning, we believe. Unless we are mistaken the method adopted is that on page 825 of the "Almanac" (the last paragraph).

**COLOUR-GRAPHY.**—Will you kindly inform me which is the most practical handbook on producing prints (not transparencies) in natural colours? I am starting to work the superimposed three-carbon film method.—C. E. DOYLE.

There is very little in the textbooks on making three-colour prints. For negative-making and colour-photography in general, you cannot do better than "Colour Photography," by Bolas, Tal-ent, and Senior, published by Marion and Co.

**PERPLEXED.**—If you wish for a vigorous black tone and a fair gloss, we should recommend you to select one or other of the collodion papers, which you will see advertised in our pages, and in the "Almanac." But we must confess to thinking that you cannot expect to decrease expenses by discarding your present paper.

**COPYRIGHT IN AMERICA.**—Could you tell me through JOURNAL how to get photographs of pictures copyrighted in U.S. America, and about what the fee is if it is possible to do it?—EDMOND WALLIS.

We do not know how you can make the photographs copyright, as one clause of the American Copyright Act stipulates that a copy must be deposited at Washington prior to publication in America or any foreign country. If you have the pictures copied in the States you can no doubt register your copyrights there.

**ENLARGING.**—Will you kindly tell me the necessary equipment for bromide enlarging by incandescent light, and what size condensers to produce good 12 x 10 prints?—KNOWLEDGE.

How can we tell you what size your condenser should be unless you state the size of the negative? But surely you can measure your negative from corner to corner. You had better get an elementary book, such as "All About Enlarging," by Somerville.

F. H. H.—The proper course is to write to the Queen's Private Secretary, the Hon. Sidney Robert Greville, addressing him wherever the Queen is for the time being.

**MOUNTANT.**—1. Can you recommend a good adhesive, suitable for mounting photographs (silver prints) to crystoleum (bent) glasses. I have tried several, but they have all spotted more or less in time. 2. Also, could you say what special method is used for fixing without leaving bubbles.—I. H. B.

The usual mountant is starch, but we doubt if you will find any which will answer well for bromide paper. It is usual to employ the thinner albumen paper for crystoleum. Use starch paste as made in the ordinary way, but thinner—about the consistency of treacle when cold. 2. Apply an ample coating to the picture side and to the concave side of the glass, and work the print into contact all over, commencing from the centre and working outwards. Finally lay the glass on a soft pad and rub the print in circles with a hard tool (the butt handle of a knife), laying a piece of tough parchment paper over the print.

E. TAYLOR.—We should say that the print is not toned by the usual processes, but is tinted by hand.

**INVENTOR.**—You had better take out provisional protection. Address the Patent Office, 25, Southampton Buildings, Chancery Lane, E.C., for directions and circular of costs. Both the ideas seem promising, though we cannot say much from the brief particulars.

**COLLODION PRINTS.**—I should be pleased if you would give me a few instructions on enamelling collodio-chloride prints—viz., 1. How to make up gelatine solution; also 2, collodion enamel; and 3, thinning solution with method of using same?

Coat glass plates (previously cleaned with French chalk) with: Alcohol, 4 oz.; ether, 4 oz.; gun cotton, 50 grains. Soften the print in water, and as soon as the collodion has set, slide the plate under the print, remove in contact, squeeze, and set to dry, pasting a backing paper about half-way through this latter process.

**STAINED NEGATIVES.**—I have some negatives (Ilford plates) taken by my late son in the Guiana Forest. I put them away safely some four years ago, and yesterday on inspecting them I find their printing qualities very much degraded, they having become very brown indeed. Can I restore their transparency, and how? I want, if possible, to print lantern slides from them. They are not varnished. OLD SUBSCRIBER.

We can only suspect that the negatives were imperfectly fixed or washed, in which case there is nothing to be done. Possibly they have been intensified with the mercuric iodide Swyle solution intensifier. If this is the case, a weak solution of Schlippe's salt will restore them. Why do you not send us one with some account of its method of production?

T. V. T.—Messrs. Dallmeyer, of Newman Street, W., have made such cameras for the same purpose as the one you name.

**POSTCARD.**—Certainly not. The copyrights are probably the publisher's, to whom you had better apply. It is not necessary for a copyright work to be so marked.

**ANASTIGMAT.**—The length of the studio will enable you to use the longer focus, but of course you will not get the same rapidity.

Owing to lack of space a number of replies to correspondents are unavoidably held over until next week.

\* \* **NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Colour Photography. The exhibition opened at these offices in January will close to-morrow week (Saturday), March 3.

Colour Photography. Some practical notes on landscape colour photography and on the printing of the transparencies appear by Edwin T. Butler. (P. 145.)

Colour Photography. Some further experiments in the bleach-out process have been made. (P. 146.)

Arion von Hübl has made some further experiments with the cyanine dyes as red-sensitisers of collodion and gelatine emulsions. (P. 147.)

Losses to the amount of £25 were inflicted on vendors of improper cards last week. (P. 157.)

Fourpenny handbooks are understood to be the next thing in the photographic publishing trade. (P. 153.)

Photographic Societies. The president-elect of the Photographic Convention has made a suggestion which should be of profit to photographic societies. (P. 158.)

Mr. Dennis Taylor has patented new forms of the “Cooke” lens fitting of the use of separate parts as lenses of double and triple length. (P. 152.)

Technical specifications of plates for various purposes are given by Mr. E. K. Mees in concluding the articles on sensitometric tests. (P. 143.)

The principles of multiple-gum and an account of a new ready-gum paper were discussed at the Croydon Camera Club last week. (P. 148.)

## EX CATHEDRA.

### The Proposed Exhibition in Paris.

The prospects for the proposed international exhibition of photography in Paris now turn out to be distinctly less promising than we suggested in a somewhat pessimistic note a week or two ago. We then recommended a suspension of judgment as to the probable success of the exhibition until the attitude of the important photographic bodies in France was known. A circular has now been issued in which it is officially announced that certain bodies will abstain from all participation in the exhibition. These bodies are the “Chambre Syndicale des Fabricants et Négociants de la Photographie,” the “Chambre Syndicale Française de la Photographie,” and two other similarly representative organisations which express the feeling of the photo-engraving and postcard industries. The first-named of the above “chambres” is a union of the important photographic manufacturers and dealers in France, including such firms as Lumière, Gaumont, Mackenstein, Turillon, and Krauss, and its decision not to co-operate in the proposed exhibition must inevitably mean that, so far as French manufacturers are concerned, the exhibition will be *non est*. The “chambres” have further expressed their decision to limit their support of future exhibitions to those which are either officially organised in France, are organised abroad and officially supported in France, or are arranged by “syndicale” bodies. A similar decision has been formed and officially published by the French Photographic Society and the Photo-Club of Paris, which associations include all the representative men in scientific and pictorial photography, and by both of which it is announced that support will not be granted to exhibitions which are not organised officially or by a union of photographic societies. We have no reason to doubt that all these bodies are acting in the best interests of the photographic community, and with special knowledge of the conditions of a successful exhibition. In the absence of their support, any exhibition must be an anachronism—an international exhibition in Paris with France unrepresented.

\* \* \*

### Professional Colour Photography.

We learn from the newspapers that the studio opened in Berlin not long ago for portraiture in natural colours has had the honour of numbering the German Emperor amongst its sitters: or rather a special studio was prepared at the Monbijou Palace, where for an hour and a half one afternoon the Kaiser submitted himself to the mercies of a staff of fifteen electricians and assistants, by whom altogether sixteen negatives were obtained of His Majesty. During the sitting the Kaiser donned three costumes, being finally photographed in the uniform of the Garde-Jaeger. The incident will no doubt create renewed interest in the

technical methods by which three-colour negatives of such a mobile personage as Wilhelm II. could be obtained with satisfaction. At least one other studio in Germany is employing colour photography commercially, and, unless we are mistaken, it will not be long before we hear of similar projects being launched in London. We understand that in the case of the Berlin studio the total exposure for all three negatives has been cut down to about twelve seconds.

\* \* \*

### Home Sensitising Plates.

Notwithstanding the excellent makes of panchromatic plates which can be obtained commercially, it is generally acknowledged that the best results are only obtainable by bathing the plates. We would call particular attention to von Hübl's paper, which appears elsewhere, for it contains an important statement on this point, namely, the use of alcohol in the bath. This not only confers greater colour-sensitiveness on the plates, but does away with the washing, which has hitherto always been considered essential. One of the difficulties in the home sensitising of plates is the drying, though this really should not present much difficulty. If those who wish to undertake this will provide themselves with a tin trunk or box, the lid of which will shut close, they will be able to dry plates within three hours at least by the use of anhydrous chloride. A dish of fragments of this salt should be placed at the top of the box, not the bottom, for it is well known that damp air rises, and therefore if the chloride be placed at the top it will dry the air much quicker than if placed below. Then if the box is placed near a fire or in a warm room the plates will readily dry. A wooden box should not be employed, as the porous walls will allow moisture to get through, so that metal boxes, or wood boxes metal lined should alone be used.

## PRINTING PROCESSES.

### XIX.—CARBON (Continued).

IN the previous article (see page 103 *ante*) it was assumed that the ordinary single transfer paper was being employed. With that the soaking in water, prior to squeegeeing the exposed tissue upon it for development, need not be much longer, if any, than that of the tissue itself. With thick and rough drawing papers, however, such as are now so largely used for carbon pictures, the case is somewhat different. With them the soaking should be much longer. If the temperature of the water be low, say 45 or 50 degrees Fahr., as it usually comes from the tap at this time of the year, two or three hours should be given. But if it be at the summer temperature of 65 deg. or 70 deg. half an hour or so will suffice. It is a good plan when the tap water comes in very cold to add a little warm to it, so as to bring it up to about the above higher temperature. In mounting the exposed prints on very rough paper it is advisable to allow them to get a little softer in the water than when using smooth paper, and to use the squeegee with more pressure so as to ensure intimate contact in the minute hollows of the paper, thus avoiding blisters in the development. It is also a good plan to allow a rather longer time to elapse between the mounting and the development than is necessary when using smooth papers.

There are one or two points in connection with the exposure of the prints that may well be referred to here. One which may cause trouble to a beginner in the carbon process is what is known as the continuing action of light—that is to say, the carbon image goes on printing, or becomes developable to a greater extent the longer it is kept, even when preserved in absolute darkness. Thus if

a print is put aside for some hours after printing it will turn out considerably darker than it would have done had it been developed directly it was taken from the frame. This darkening, it should be explained, is not a regular one, as it depends very much upon the prevailing atmospheric conditions. If the air is cold and dry the progressive action is but slow. If, on the other hand, it is damp and humid, it proceeds rapidly, and under these conditions a material difference may be observed, even after two or three hours' keeping. Hence allowance should be made for this in the printing, according to the state of the atmosphere—that is, supposing the prints are not developed as soon as printed. By taking advantage of this property in bichromated gelatine, and using judgment, the exposure in the printing may be considerably curtailed, and that without detriment to the result. In our issue for last week, under the heading of "Photo-mechanical Notes" (see page 130), is an interesting note on this subject.

Another point to be borne in mind is that the tissue is, proportionately, more sensitive when it is exposed in a strong light than it is in a feeble one. For example, if a given negative requires, say, four tints by the actinometer in a bright summer light, it will require quite five tints in a dull winter one to obtain a similar depth in the print.

In the previous article it was mentioned that there is very great opportunity for local treatment in the development of carbon pictures—portions may be lightened to almost any extent, while others can be kept subdued. The development of a carbon print being simply the removal, or washing away, of the more or less partially soluble pigmented gelatine, the hotter the water used the more pigmented gelatine will be dissolved. For example: the pigmented coating that would be practically unaffected by water at, say, a temperature of 90 deg. or 95 deg. would freely dissolve in water at 120 deg. or 130 deg. Hence, if a picture were being developed at the former temperature and a stream of water at the latter heat be poured on certain parts, those will dissolve and so become lighter, while the other parts will be unaffected. This dissolving, or washing away, may be further accelerated, or more closely localised, by using a flat camel-hair brush, which will materially aid in the removal of the pigmented coating.

Where much local treatment, or "faking," is to be done the print should receive but a minimum of exposure, and the main development be conducted in very cool water, as then the parts to be lightened are very amenable to the hotter water and to the brush, due to the fact that the film, generally, is in a more soluble condition than if the print had been more exposed. Hence, when much local treatment has to be done, anything like over-printing should be avoided. Also it is as well to commence the work as soon as the tissue is stripped off the support—having a rough print at hand as a guide. We then proceed to remove some of the coating from the parts that are required to be the lightest—either by the application of hot water or of the brush, or of both together—and then allow the print to rest for a short time, still keeping the water cool. The brush and hot water treatment may be repeated as desired; but it is desirable that the final development of the picture should be spontaneous. By this procedure any palpable evidence of faking will not be noticeable in the finished result.

If the pictures are printed with a white margin, whether on rough or smooth paper, they should be dealt with directly the tissue is stripped, by clearing off the soluble coating with a piece of soft sponge dipped in hot water. The same treatment may be applied to the margins of vignettes; in this case, however, the sponge should be used with a light circular motion, but not in such a way as to encroach on the shading of the vignette. By this treat-

at the margins of the pictures will be obtained much better and cleaner than if they were allowed to develop simultaneously.

There is another and more drastic method of local treatment, though it is scarcely to be recommended to novices in carbon printing. Alkalies have a solvent action on the gelatin, though if a brush charged with, say, one part of ammonia to ten of water be passed over certain portions of the picture, those parts will be rendered more soluble than the others, and thus become, proportionately, more developed as the development proceeds. If this method be adopted it is advisable that the printing be carried a little

deeper than with the previous one, also that the "faking" be deferred until a somewhat later stage of the development; indeed, it may be left till it is nearly completed.

If a number of prints be developed in the same water it will become very frothy, and the bubbles an annoyance in working. The remedy, however, is very simple. If two fingers be rubbed on a piece of soap, and the water stirred with them, the bubbles will at once disappear and will not form again.

The double transfer method of working, and the sensitising of the tissue to suit different classes of negatives, will be dealt with in a forthcoming article.

## THE INTERPRETATION OF SENSITOMETRIC TESTS.

### III.—THE DEVELOPMENT CONSTANTS.

In a former article (B.J., June 9, 1905) it was stated that development could be shown to be a heterogeneous reaction occurring in accordance with the equation

$$\kappa = \frac{1}{t} \log \frac{D_{\infty}}{D_{\infty} - D}$$

where  $\kappa$  is the velocity constant of development. We may, in the above equation, substitute for  $D$ ,  $\gamma$ , the development factor. Referring to the figure (1) given in the second article of this series we may express  $\gamma$  as the slope of the straight line tangent to the plate curve, and since a slope is expressed as

become  $B'$ , while  $\gamma$  will become  $\frac{B'C}{AC}$ , i.e.,  $\gamma$  is proportional to  $D$

So that we can apply the development equation to  $\gamma$  and it becomes

$$\kappa = \frac{1}{t} \log \frac{\gamma_{\infty}}{\gamma_{\infty} - \gamma}$$

or, writing the equation in another form,

$$\gamma = \gamma_{\infty} (1 - e^{-\kappa t})$$

Fig. 4 represents the straight line portion of a plate in which the constants  $\gamma_{\infty}$  and  $\kappa$  of the above equation are respectively 2 and .2. The slope is represented for every minute's development from 1 to 13, and it is easy to see how the extra minute has less and less effect as the slope approaches  $\gamma_{\infty}$ , until finally no greater slope can be obtained, however much we develop the plate. In the same way, fig. 5 shows the increase of  $\gamma$  for the

Fig. 3.

tangent of the angle, we mean, by  $\gamma$  the tangent of the angle which the straight line makes with the axis—thus, in fig. 3, if the curve has a straight portion cutting the axis at A, so that OA will be the logarithm of the inertia, then  $\tan BAC$ , i.e.,  $\gamma = \frac{BC}{AC}$ , if BC be drawn perpendicular to the axis.

Since (when there is no potassium bromide in the developer) point A remains constant while  $\theta$  increases, we see that density B corresponding to a logarithmic exposure C will

Fig. 4.

same plate with increasing time of development. It will be seen that  $\gamma$  mounts rapidly at first, but soon reaches a limit beyond which it cannot go.

$\gamma_{\infty}$ .

This limit, which, so far as we know at present, depends on the plate, and on the plate alone, is termed  $\gamma_{\infty}$  because it is the  $\gamma$  reached on infinite development.  $\gamma_{\infty}$  is clearly the density-giving power of a plate, and governs what has been termed the "character" of a plate—i.e., low  $\gamma_{\infty}$  makes a soft plate, high  $\gamma_{\infty}$  a plate capable of strong contrasts.

A plate that can be "forced" in development when under-exposed will have a high  $\gamma_{\infty}$ .

The rate at which a plate develops during the earlier part of its  $\gamma, t$  curve is proportional to  $\kappa \chi \gamma^{\infty}$ .

Now,  $\gamma_{\infty}$  depends on the plate, but  $\kappa$  depends also on the developer, on the developing temperature, and so on.

With the same plate, if we double  $\kappa$ , we halve the time necessary to get the same  $\gamma$ . We can increase  $\kappa$  to almost any extent by increasing the concentration of the developer, so that in making sensitometric measurements of  $\kappa$  we must carefully define the developer and temperature used. Since the chemical reactions of the ferrous oxalate developer are better understood than those of any other developer, ferrous oxalate makes a good standard, and a convenient standard is a developer containing 56 grammes of iron per litre at a temperature of 20 deg. C.

We see that for ease of development it is desirable to obtain a high  $\kappa$ , but it is much more important to obtain a high  $\gamma_{\infty}$ .

In fact, of all the constants of a plate, I should consider  $\gamma_{\infty}$  the most important. For example, if a plate is being used for extremely under-exposed focal-plane work, then a high  $\gamma_{\infty}$  is far more valuable than a high speed.

Fig. 5.

For instance, the following two plates gave practically identical results, by eye judgment, at F.3.5, 1-500th sec.

Plate.	Inertia.	H and D No.	$\gamma_{\infty}$
1	.260	131	1.88
2	1.190	28.6	4.01

It is for this reason that slow plates can frequently be used for extremely short exposures, because the high  $\gamma_{\infty}$  often associated with a slow plate compensates for the low sensitiveness. Values of  $\gamma_{\infty}$  may range from 1.5 (low) to 3.5 (high), or even above or below these limits.  $\kappa$  from .03 (low) to .2 (high).

As a general rule,  $\kappa$  is higher in a slow plate than in a fast, and it almost always decreases if the plate is kept.

The constant  $t_{\gamma 1}$  is the time necessary to reach a  $\gamma$  of 1 and is easily calculated from the values of  $\gamma_{\infty}$  and  $\kappa$ . It is of use in comparing the rates of development of two plates which have widely different  $\gamma_{\infty}$ 's. The constant 0 is the measure of the optical opacity of the unexposed plate to blue violet light (W. length 4,300). It is of importance, because the latitude of the plate (i.e., the range of exposures which the plate can render correctly) depends upon it (this has been shown theoretically—see B.J., November, 1904).

The constant  $\chi$  for colour-sensitive plates is the ratio of the blue sensitiveness to the yellow sensitiveness. In

order to measure it, plates are exposed, as for speed-testing, but with first a 4 per cent. solution of potassium chromate, and, secondly, a 2 per cent. solution of copper ammonium sulphate, in a 1 cm. thick cell between the light source and the plate; the light source being, as before, acetylene screened, to give the spectral composition of daylight. The resulting inertias are then measured and the ratio:—

$$\frac{\text{Yellow Inertia}}{\text{Blue Inertia}} = \frac{\text{Blue Sensitiveness}}{\text{Yellow Sensitiveness}} = \chi.$$

$\chi$  may vary in commercial plates from 20 for rather poor erythrosin plates to 5 for panchromatic plates, or 2 for plates with subdued blue sensitiveness, while for bathed plates it may become 1 or slightly less. The lower  $\chi$ , the better the colour-sensitiveness. The other three measurements which should be made for a plate to be tested deal with the fog, i.e., the velocity of blackening without exposure, the grain, and the evenness.

The last of these is easy to measure, but scarcely worth the labour involved. Owing to the extreme variability of fog, and the sensitiveness which it displays towards external influences, it has not been found possible to measure the extent of the fog due to the plate itself with any regularity. All that can be done, in fact, is to make general statements by eye comparison. We may hope that, later on, measurements may be placed on a more satisfactory basis.

#### Specifications for Good Plates.

The following specifications for plates for different purposes may be taken as those which I personally should choose, and which the platemakers, in the present state of knowledge and technical skill may be reasonably expected to supply.

All plates should be quite free from perceptible fog, be evenly coated, and have a reasonably fine grain.

For a portrait plate (colour sensitive):—

$i$	=	.125
$\chi$	=	8
$\gamma_{\infty}$	=	2.2
$\kappa$	=	.080
0	=	20

For a landscape plate (colour sensitive, slow):—

$i$	=	.500
$\chi$	=	3
$\gamma_{\infty}$	=	2.5
$\kappa$	=	.130
0	=	20

For a hand-camera plate for forcing in development, some result being more important than truthful gradation:—

$i$	=	.150
$\gamma_{\infty}$	=	4.0
$\kappa$	=	.060
0	=	20

For a process plate for line work:—

$i$	=	3.0
$\gamma_{\infty}$	=	4.0
$\kappa$	=	.150
0	=	7

For three-colour and orthochromatic work the corresponding plate bathed in an isocyanine dye. If sensitised in the emulsion  $\chi = 5$ .

For a transparency plate:—

$i$	=	5.0
$\gamma_{\infty}$	=	1.8
$\kappa$	=	.300
0	=	10

Individual workers will probably agree that some of these specifications may be altered to agree with personal preferences,

they may be useful as suggestions of what may be made, not, be it understood, what might be made, if plating were in a more advanced state than it is at present. Of course, some desiderata are impossible from their very nature. For example, a published specification for a process included a plate with a thin film to avoid irradiation, but a considerable latitude. Now, since latitude depends on it is clear that considerable latitude is incompatible with free-

dom from irradiation, and a choice must be made as to what latitude and what irradiation are to be obtained. The question of complete colour sensitometry, including the testing of panchromatic plates for three-colour work, must be deferred for the present. In conclusion, I would hope that these papers may be of use as explaining the results which are obtained in sensitometry, and the limitations which occur in the application of these results. C. E. KENNETH MEES.

## COLOUR PHOTOGRAPHY.

### TRI-COLOUR WORK WITH A SINGLE EXPOSURE CAMERA.

Colour photography is now an accomplished fact. The difficulties in securing results are still considerable, but when there can be no question that the results recompense the extra trouble involved. Colour prints are now obtainable both as transparencies and as prints on prepared paper. Transparencies offer the most tempting field to the worker in the colour photograph.

By a convention, prints on paper are most in demand by the public, but to the lover of colour full satisfaction is only to be obtained in transparency work. No medium of artistic representation has ever offered such rich colour representation as is seen in dyed gelatine transparencies.

In oil painting the high-lights are frequently loaded with colour in order to catch the light, and by this device the effect of brilliancy and sparkle is secured. While, on the other hand, the range in shadow is increased by transparent glazing and fitting of the rich and subtle detail of half tone and deep shadows.

Transparencies, in a somewhat similar manner, by a wide range of light and shade lend themselves to the representation of even richer effects. A print on paper is shown by light reflected from the white ground, and transmitted through the overlying colour. And this reflected light is necessarily weaker and of narrower range than that of transmitted light.

Transparencies transmit the light directly, the stronger light giving details in a depth of shadow many times stronger than that which would appear black on a white ground. It is for this reason that three-colour photography is seen at its best in superimposed triple films printed, and dyed in colours, each transmitting a band equivalent to two-thirds of the spectrum.

A medium of expression is naturally adapted to the colour and one which in its own domain has added an unique value to artistic representation. My own work in colour photography has been directed chiefly to the production of an instrument which at one exposure should yield triple negatives, each exclusively registering one of the three elementary colours of the spectrum.

#### A One-exposure Camera.

In the examples of my work shown in the exhibition have been taken with a camera I designed with this object (see the *Almanac*, 1906, p. 856). Through a single lens the red, green and blue negatives are simultaneously exposed, the variations being corrected in intensity, so that the exposure for each negative is the same in time.

The results exhibited are from negatives taken either by my quarter-plate or half-plate camera.

The quarter-plate camera is sufficiently compact to carry in ordinary photographic excursions, and I have not incidentally in the course of a walk been struck by a subject, unaided by the camera and stand, exposed the plates, repacked, and continued my journey in from five to ten minutes from the time I was arrested by the view.

#### Exposures.

For portraits and evenly-lighted landscapes with strong foregrounds, the time of exposure should be equal to that required to change P.O.P. to the standard tint.

For ordinary landscapes I expose half actinometer time.

For brilliantly-lighted landscapes one-fourth and one-sixth of actinometer time, and as short as one second for afternoon sky and cloud effects.

I have secured fairly satisfactory results of sea and cloud in one quarter of a second.

It is unnecessary to consider the ratios of exposure when using my camera, the screens and their position in the camera regulate the comparative degree of light each plate is to receive.

I find the negatives come out with a very fair degree of regularity when the time of exposure lies between say 10 and 15 seconds and 3 or 4 minutes, although very longer exposures are practicable.

It is as easy and simple with a single-exposure tri-colour camera to take views as with the ordinary snapshot, but after this the difficulties commence.

#### Developing the Plates.

Development of the plates is a process identical with that of ordinary development for black and white, but in so far as three negatives have to be produced for one subject, and each has to bear a correct ratio to the others, certain details have to be observed. Each of the three negatives should be nearly as possible exhibit in the highest light, white, the same degree of density, and the range of density from white light to deep shadow should be similar in each. The negative taken through the red screen, as a matter of fact, is usually steeper than those taken through the green and blue screens. The best results are secured when the period of development for each of the three negatives in the same developer is constant, but when exposures have been made under anomalous and difficult conditions a little latitude for approximate correction is permitted by varying the relative time of development. I generally find two to three minutes' development sufficient with metol or edinol developer.

#### Printing the Monochromes on Dyed Gelatine Films.

Having obtained promising negatives, I have found it convenient to gauge their densities, and for this purpose use a density gauge, by means of which the greatest density (high light) of each negative is matched to a standard. The numerical equivalent is noted on each negative, and this is an index to the actinometer time required in exposing the positive. For printing the positives, thin glass plates coated with gelatine and subsequently dyed to a standard in an appropriate aniline dye are used.

They are sensitised by immersion for three minutes in a 4 per cent. solution of potassium bichromate, and dried quickly in the dark. The colour of each positive plate is complementary to the taking colours of its respective negative.

The negative taken through the red screen is printed on blue-stained gelatine-coated thin glass, though greater sharpness is

given if a black tone positive be converted to a ferricyanide blue. This is effected by bleaching in potassium ferricyanide and treating the bleached image with ferric chloride.

The negative taken through the green screen is printed on pink-stained gelatine, while the negative taken through the blue screen is printed on yellow-stained gelatine, with which the respective plates are coated.

Each positive should be printed so that the gradient is the same in each. The positive plates are placed with the back next to the face of the negative, and printed through the back of the glass. It is advisable to expose the printing frames in short tunnels to cut off side light.

If prints are made in direct sunlight, the face of the plates should be at right angles to the axis of light. In developing the prints, they should be washed for a few minutes in cold water to dissolve out the sensitiser. They should then be allowed to remain without rocking in hot water about 100 to 120 degrees, which dissolves the unaltered gelatine, and leaves the image in colour. When sufficiently developed they are set in cold water.

Having made sure that the relative strength of colour on each is properly adjusted to the other two by re-dyeing or washing out, when it is necessary, the elements are allowed to dry, and are then put together.

I prefer glass plates to films, because I find them easier to manipulate at each stage of the process, namely, in staining, sensitising, printing, developing, and registering. The slide-or transparency is made by simply putting the blue and red prints face to face, and the yellow print with the face towards the back of the red, the whole being held together temporarily with clips until the corners are fixed with adhesive and the edges bound.

#### SOME NOTES ON THE BLEACH-OUT PROCESS.

The following notes on the bleach-out process of colour-photography, examples of which, by Szczepanik process are to be seen in our Colour-Photography Exhibition, are abstracted from a paper by Dr. Neuhauss and Professor Kümmell in two of our German contemporaries.

Neuhauss has used the ultramicroscopic method of examination as worked by Siedentopf and Zsigmondy, and finds that many solutions of dyes are not real solutions, but that ultra-minute particles of the dye are suspended in the solvent, whether this be alcohol or water. Another fact is that the colour solutions differ with differing concentrations, and this explains why different mixtures of the bleach-out dyes show different sensitiveness. Dr. Neuhauss has observed that one film may be dark and comparatively insensitive, whilst two films each lighter, and yet both together containing the same amount of dye as the dark one, are most sensitive.

The age of the solution also affects the colour and sensitiveness. Thus, methylene blue solution shows not only blue particles, but also a diffuse red colour, and, by keeping, the coarse particles become larger and sensitiveness is lowered. Erythrosine, when dilute, shows an intense yellowish green diffused light. In stronger concentrations this becomes greyish green, and large yellowish-red particles are seen. In stronger solutions the diffuse light becomes yellow-red and the number of particles much greater.

With some solutions the particles polarise light. Uranine added to a mixture of dyes produces a characteristic green diffused light, and frequently reduces the number of visible particles. The author finds that dye solutions which show strong diffused light are the least sensitive for the bleach-out process, and that those which contain innumerable minute particles are more sensitive than those containing coarse ones.

A SOCIETY for Workshop.—Another effort is to be made to establish a photographic society in Workshop.

A PROPOSITION is on foot to mark the fiftieth anniversary of the discovery of the dye-stuff "mauve," by which the foundation of the aniline colour industry was laid by Dr. W. H. Perkin, F.R.S., by the presentation to Dr. Perkin of a portrait in oils of himself (to become the property of the nation at his death), by the execution of a marble

To get all three elements in intimate contact, the yellow may be transferred to the blue print and the red placed with its face to the face of the blue-yellow positive. Some of the prints exhibited are made in this manner.

It is not necessary to balsam the elements together.

The method of printing I have adopted is one which I have selected after working most of the methods currently in use. For the reasons given above, I prefer transparencies to prints on prepared paper, but, as is well illustrated in the exhibition, exquisite results are yielded by the latter method. It is probable that a wise eclecticism will in the end yield the most facile and correct results.

My own experience is that whichever method be adopted, difficulties are experienced. I have thought there was a gain in using gelatine-coated plates from which a sensitive silver salt was omitted, since there is a saving and simplification in the omitted step for its removal. If the silver salt, which merely serves the purpose of following the development, be omitted, it is needful to substitute some reagent which shall serve this purpose, and the natural agent which presents itself is the dye in which the print is finished.

Certainly in my most successful endeavours this method has yielded results in the most direct manner. Each element dyed to a standard, and properly exposed behind correct negatives, has under correct exposure and development yielded satisfactory results without either washing out or re-dyeing.

Such an achievement, could it be insured with anything approaching invariability, would be both simple and direct, but the varying conditions under which colour photography is practised necessarily in the present stage of the art leaves mechanical accuracy and facility a goal still greatly to be desired.

EDWIN T. BUTLER.

Further experiments with sensitisers for this process have proved fourth. Celloidine dissolved in glacial acetic acid, with a few drops of 30 per cent. caustic soda solution reduces the time of exposure to one-fourth. Celloidine dissolved in glacial acetic acid, with a few drops of turpentine as sensitiser, may be used instead of gelatine, but erythrosine must not be used, and a satisfactory red dye has not yet been found. Experiments in the direction of developing the pictures have not been very successful, though hot water may be useful, as also, in some cases, immersion of the prints in a 10 per cent. solution of potassium iodide, to which a few drops of chloride of gold solution have been added. Sometimes it is advantageous to dip the prints subsequently into hypo.

Professor Kümmell, who has been experimenting, has obtained the red fog, which was first noted by Neuhauss, when too much erythrosine is used. He points out that erythrosine may be the tetrachlorobromo, tetraiodo, or diodo fluoresceine compounds of soda, and he finds the latter the most sensitive, and that the ammonium salt is more sensitive than the soda salt. Pure dyes are less sensitive than when they contain a small impurity of iodine.

The best results are obtained by using three parts of tetraiodo fluoresceine, and one part of di-iodo fluoresceine. The addition of colloidal solutions of gold considerably increased the sensitiveness in many cases.

In order to coat the sensitive mixture on paper, Kümmell waxes a sheet of plate glass, spreads the dye mixtures thereon, and then allows it to dry, damps the surface with a wet brush, and squeegees a sheet of paper thereon, places under a weight for about ten minutes, and then dries, when the paper and gelatine will spring away from the glass.

bust of Dr. Perkin to be placed in the rooms of the Chemical Society, and by the establishment of the "Perkin Research Fund" for the promotion of chemical research. These objects have received the support of an influential and distinguished committee of which Professor R. Meldola is chairman, and a public meeting to forward them will be held at the Mansion House on Monday next, February 26, at 3 p.m.

## RED-SENSITIVE PLATES.

The following notes are abstracted from an article by Freiherr von Hübl in "Das Atelier des Photographen," and, in conjunction with the notes on pp. 771-773 of the "Almanac," give us a very good idea of the present position of the subject. That the last word has been said on "panchromatising" is doubtful, though the only possible direction of advance would seem to lie in the discovery of a dye which would still further increase the sensitiveness of the silver salts to the less refrangible rays, so that we could obtain an effect true to visual luminosities, without a colour screen, and with short exposures as we now give.

\* \* \* \* \*

In the early days of photography orthochromatic plates—that is, yellow and yellow-green sensitive plates were satisfactory, but as soon as the reproduction of oil paintings, etc., became general, the want of red and orange sensitiveness was soon felt, and since colour-photography and three-colour work have come to the front this has become a crying need. The first sensitiser to at all answer requirements was cyanine, but the troubles with this, such as fog, spots, flatness, and reduced sensitiveness were heartbreaking, and the use of these troubles was never determined. Such substitutes as grosine, wool black, alizarine blue bisulphite, etc., were not such powerful sensitisers.

In consequence of the high sensitiveness of the gelatine plate, comparatively weak sensitisers may be used, and the commercial orthochromatic plates will give good results through red filters, only the exposure must be increased, in some cases perhaps a hundred times. With collodion emulsion, in consequence of its low sensitiveness, these dyes are but of little value, and rose-bengal-silver used, which only sensitises for yellow and green. With a narrower filter that cuts out the blue and green the reds may be obtained efficiently bright, but they are actually photographed by the yellow rays that they reflect. Very long exposures are required, otherwise an unsatisfactory rendering of the reds is the result.

Ethyl violet, first suggested by Valenta, was a distinct advance, and sensitises collodion emulsion like cyanine, without its disadvantages. This dye is interesting because it is so stable to light and yet produces such a decided action, which far surpasses that of eosine and proves that the fugitive character of the dyes does not come into play, but that the dye and silver bromide compound is the factor, whether the action of this be chemical or physical. Ethyl violet may be used with gelatine plates, but is not effective, though its action has not been so carefully studied as new class of dyes was discovered, which were far superior to all others, giving good action in the green, yellow, and orange, and thus taking the place of eosine and cyanine.

## The New Isocyanines.

The first of these panchromatic sensitisers was Miethe's ethyl red, which sensitised the plate for green, yellow, and yellowish-orange, and this required a somewhat lengthy exposure behind the red filter; until it indicated the path which later has been followed so far by Dr. König in spectral red sensitising.

All these dyes belong to the cyanine group, of which practically the old cyanine was the only example, and this was useless in dyeing technique because of its fugitive character. When chinine is dissolved under certain conditions certain basic substances, chinoline, quinidine, chinaldine, etc., are formed, these form the material for the preparation of purple red, blue, and violet dyes—the so-called isocyanines. They are all fugitive dyes, the solutions of which are colourised by acids, and all of them are sensitisers. Agreeable to the general rule, these dyes sensitise for those colours, to which they—or, rather, that colour, which they impart to silver bromide—is complementary. That is to say, a purple red, violet, or blue cyanine will sensitise for green, yellowish-green, or green respectively. This does not imply that the sensitiveness is confined to these particular regions, each extends to the neighbouring colours with differing intensities and extent. Thus, a purple-red cyanine sensitises not only for the green, but also for yellow-green and blue-green, perhaps also for yellow and orange, for these can—a certain

intensity assumed—in the sum be called green, and thus be the complementary to purple.

There is a close connection between the spectrum sensitising band and the absorption of the dye, and from the latter one may deduce the extent and the intensity of the assumed colour-sensitiveness. The extension of the band of sensitiveness is of the greatest importance, for it shows what colours will act on the plate. The purple-red erythrosine, for instance, sensitises only for yellow-green and the neighbouring colours; whilst one of the cyanines of almost the same colour sensitises the plate to all colours from blue-green to orange. These broad sensitising bands are the great value of the cyanines.

So far, dyes have not been discovered which will sensitise for the whole stretch from blue to red, and we must choose between those which sensitise from the blue-green to the yellow-orange, or those from green to red-orange; to the first class belong ethyl red and pinaverdol, which require a long exposure behind the red filter; whilst the latter include pinachrome, which does not act so well behind the green filter. These dyes do not sensitise for the extreme red, and therefore the plates may be safely worked in a deep red light.

The newer cyanine pinacyanol, discovered by Dr. König, sensitises very strongly for red, and is the first actual red sensitiser, and may even be used with collodion emulsion. It has a maximum between B and C, and reaches to E b. Plates sensitised with it correspond to all the theoretical requirements for the blue-printing negative, and require, compared to all other sensitisers, a considerable reduction of exposure.

The accompanying chart, which is the result of the experiments of von Hübl's assistant, Herr G. Winter, puts in a nutshell the sensitising power of these dyes. The results were obtained with a

Thorpe diffraction grating spectrum and a Nernst lamp. I. shows the sensitising power of the ethyl-violet, it is comparatively narrow, and includes only the yellow and orange. II. shows the effect of pinachrome, a much broader band, and yet it is not a true red sensitiser. III. shows the effect of pinacyanol, and we have here a true red sensitiser, whose action extends to a. The effect of another cyanine, called pinachrome blue, is shown in IV., and it behaves very much like III. Dicyanine, which far surpasses these last two in red sensitising, was briefly described in Eder's "Jahrbuch," 1905 (see "Almanac" loc. cit.), but the results obtained were unreliable, because the dye was not pure. As will be seen from V., the pure dye sensitises from almost A to E b, with three maxima at B, C<sub>2</sub>D, and behind D. Naturally, this permits of much shorter exposures behind the red filter than all other dyes.

All these dyes can be used for gelatine and collodion, and have no tendency to fog, only a perfectly safe dark-room light must be used. As all red glasses transmit rays from B<sub>2</sub>C, clean negatives cannot be obtained, and it is advisable to use a blue-green light, which may be obtained by using gelatined glasses, one soaked in naph-

thol green and the other in methyl-violet. Naphthol green is the only green dye that can be used, as other greens, such as acid or fast green, let through a band in the red. The naphthol green solution should be acidified with a few drops of glacial acetic acid, and the methyl-violet be rendered alkaline with a little borax. With properly stained films, the light transmitted by the two in combination is about the F line.

#### Collodion Emulsion.

For collodion emulsion 1 per cent. of a 1:1000 solution of the dye should be used, and after the plate has set it should be bathed in water or rinsed under a rose tap. This washing considerably increases the sensitiveness, a phenomenon which has been observed with all dyed collodion emulsions, and which may be ascribed either to a deeper staining of the bromide molecule or to the part played in the exposure by the dampness. The unwashed plates work clean, but are less red sensitive. Even when added in much larger quantities the dyes do not cause fog, but the dyed emulsion soon loses its red sensitiveness, which, however, can again be renewed by the addition of more dye. This phenomenon has been observed with all cyanines, but whereas with pinaverdol the red sensitiveness disappears after some weeks, with the new cyanines it disappears in from one to two hours. The emulsion does not lose its blue colour, and this appears to be independent of the quantity of dye added.

#### Sensitising Gelatine Plates.

These dyes are excellent sensitisers for gelatine plates, and the dye-bath should be:—

Water .....	120 parts.
Alcohol .....	60 parts.
Dye solution 1: 1000 .....	1 part.

and the plate should be left in for at least ten minutes,\* and the plates should be dried as quickly as possible. This last point is very important, otherwise vigorous clean negatives cannot be obtained.

It is absolutely necessary that this semi-alcoholic bath be used, as nothing like the same high colour sensitiveness can be obtained by the use of an aqueous solution. This is strikingly shown in the case of pinachrome blue. The reason is that with water these dyes do not form solutions which will penetrate the gelatine. If an aqueous solution of these dyes is repeatedly poured through a paper filter, the whole of the dye will adhere to the paper and the filtrate be almost colourless. In contact with gelatine the aqueous solution behaves in the same way, and the bulk of the dye is deposited on the surface of the gelatine and causes fog, spots, and streaks there, whilst practically no dye penetrates the film. This peculiarity of cyanine solutions was pointed out by Häbl in 1899.

The three dyes do not behave quite the same with collodion and gelatine. With the former the sensitiveness is greater in the red than in the yellow and green; whilst with gelatine the reverse is

\* Dr. König informs us that he has determined by very careful tests that 3–4 minutes bathing is quite sufficient.—Eds. B.J.P.

the case. This is due to the absorption of the dyes in aqueous and alcoholic solution. (See "Almanac" loc. cit.—Eds., B.J.P.) The intensities differ too. With gelatine plates pinacyanol is most vigorous; with collodion, on the other hand, dicyanine is the strongest.

If a colour chart is taken with the dyed collodion emulsion, without a filter, in the case of pinacyanol and pinachrome blue, vermilion is rendered as light as ultramarine, with dicyanine the former is the lighter. The exposure is only about half or quarter of that with the undyed emulsion. The total sensitiveness of the plate is therefore about quadrupled.

In making the blue print negative only a bright orange filter is required, and the exposure increased only by about a half. The red sensitiveness of the plates is greater than the blue sensitiveness, so that these dyes are of the utmost importance for three-colour work with collodion emulsion.

The results with gelatine plates are less satisfactory, but even with these without a filter, vermilion is fully exposed and chrome yellow is as dense as ultramarine. Pinacyanol acts well, and, as already mentioned, gives absolutely clean, vigorous negatives. It might be possible that these dyes are preferable to pinachrome and ethyl-red as panchromatisers; in any case they permit of a considerable reduction of the exposure behind the red filter, and the minimum between b and F ought not to appreciably degrade the red print plate.

Dicyanine, which is the best red sensitiser, offered the opportunity of making an ideal yellow print negative. The plate for this must be sensitive to blue in the first place, and therefore if we use an ordinary plate without a filter, or a colour sensitive plate with a filter, we shall find that vermilion and chrome-yellow are alike without action, that is, they print with the same intensity of yellow.

As vermilion in the composite print must not be too yellow, it is desirable that in the negative the red should be denser than the yellow. Many attempts have been made, so far without result, to use a plate at once sensitive to red and blue. As hitherto, a red sensitiser was not available, dicyanine was tried for this result. For the filter was used an alcoholic solution of this dye, so that only those sensitising zones could act which were comprised by the differences between the absorption and sensitising bands—(see "Almanac" loc. cit.—Eds. B.J.P.)—for, as is well known, the latter, corresponding to the absorptions of the dyed silver bromide molecule, lie nearer the red.

Under these conditions only the red and violet sensitiveness of the plate could be used, that is, the red sensitiveness between A and B come into play. Exposures on a coloured chart, however, showed that there was no improvement in the yellow print negative, for chrome yellow and vermilion were of the same density. The red and yellow pigments cannot really be differentiated by their absorptions in the red, only by their absorptions in the green.

A. VON HUMB.

## GUM PROCESSES AT THE CROYDON CAMERA CLUB.

Some interesting points dealing with the gum-bichromate process were discussed and dealt with at a demonstration which Mr. J. L'Epine Smith gave before the members of the Croydon Camera Club, on the 14th inst. Several well-known workers, including the veteran gum exponent, Mr. Packham, and Mr. Arbuthnot—whose exhibits at the last R.P.S. Exhibition attracted much attention—contributed to the subject of the evening.

Mr. Smith, in his opening remarks, alluded to the hostile criticisms which had accompanied the re-introduction of the process. This had to a large extent, but not entirely, subsided. It was curious, but true, that if a photographer produced a bad carbon or platinotype print, the worker, and not the process was blamed. On the other hand, if an atrocious "gum" was perpetrated, in nearly every case the process, and not the worker, was condemned, a reversal of things which was distinctly unfair.

#### Multiple Printing.

It is not necessary to follow Mr. Smith through the more familiar details of the process, it will be sufficient to say that they were practical and explicit throughout. Mr. Smith did not favour single

printing; in his opinion it was difficult, if not impossible, to get sufficient range of tone, and depth of pigment. Moreover, with reason, the greater the number of printings, the more the control, and less the likelihood of hand-work being rendered obtrusive. Suggesting, he said, three coatings were to be adopted, then his practice was to employ a very small proportion of pigment for the first coating, together with a considerable exposure to obtain detail in the high-lights; the second coating would have more pigment and less exposure for the half-tones; whilst the third coating would have a maximum of pigment, and a minimum of exposure to secure the heavy shadows. It was necessary to grind even the finest powders with the gum on a piece of ground glass, to avoid a gritty deposit, which in some cases might be purposely sought for, and secured. For coating, he preferred a tub-sized paper, and, personally, he occasionally favoured the Autotype Company's single transfer paper, if much detail was wished for. For coating, and smoothing down, he used a cheap hair-mottler, working the brush up and down and across the paper.

At this point, Mr. Packham was prevailed upon to show his

method of softening. In left fingers a badger-hair brush was applied with light feather touches, in a sort of skip-and-jump fashion until the coating was set. Mr. Arbutnot used the same implement with much the same action, except that he never allowed the tips of the bristles to leave the paper. Mr. Smith, resuming, said that decidedly soft negatives were necessary, he generally used paper ones, sensitized, and applied to a sheet of clear glass, to facilitate registration whilst printing. Kodak's slow smooth bromide paper is excellent for the purpose.

**The "Richmond" Gum Paper.**

He next drew attention to a new process, being brought out by Dr. Richmond, of Paisley, and shortly to be placed on the market by Messrs. Houghton, with all necessary materials for working it. The coating of the paper is simplified, no expensive softener is required, and it is claimed that the prints are capable of a wider range of tone, greater shadow depth, and a higher degree of control, than any other existing single-printing method. Nor is there any tendency towards scaling. To develop an exposed print, all that is necessary is to place it in cold water for a few seconds, then on to a sheet of glass or zinc, and gently apply a wide brush up and down, and cross the paper. The rapidity of development may be judged from the fact that Mr. Smith developed two satisfactory prints well under thirty seconds each, excluding the inevitable subsequent tinkering with a small brush, to give the prints a more artistic appearance, and bring out salient features, which might, or might not, have existed in the original negative. Perhaps the most notable, and, to many, welcome, feature, which distinguishes the latest coming from others of the ilk, is that normal negatives, such as are suitable for carbon platinotype, can be used with success. Indeed, Dr. Richmond has

expressly stated that soft negatives do not give such good results. The colloid used is a secret, but its originator has intimated it is complex, and free from acid, which has a tendency towards creating insolubility.

In the discussion which followed, Mr. W. H. Rogers said he had never employed more than one coating, and saw no necessity for more. Mr. Packham suggested the use of a lithographic stone for grinding colours upon, it was far more efficient than ground glass, and by no means costly. He quite agreed with Mr. Smith that if any extended scale was to be rendered, multiple coating was essential. He also well remembered the torrent of abuse the process met with some years ago. Personally he had taken it up because results could be obtained by its aid impossible with other media. Mr. E. Salt was at a loss to understand why so many coatings were required, having regard to the fact that the finest prints he had ever seen, judged purely from a technical standpoint, were produced by their fellow-member, Mr. Hugh Allen, with his single-coated thick-film method. Mr. Arbutnot replied that, while admitting this to be the case, he doubted whether Mr. Allen's prints would permit of brush work, or other means of permitting individual expression. Without such capability the process had no valid reason for existence. For light, sketchy pictures, single-coating, no doubt, sufficed; but for depth and half-tone, several printings were, in his opinion, obligatory. If the former method was adopted, then the addition to the gum of other colloids—for instance, starch—would greatly increase the range of gradation. Dr. Richmond, apparently, had recognised this, and he thought his process most promising. He should look forward to seeing more of it when it was placed upon the market.

**THE STUDIO BLINDS.**

is a well known axiom in legal circles that "trade customs," if good law, are, at any rate, strong *prima facie* evidence as to the merits or wrongs of a case. Who the first man was to use blue and white blinds in the studio is "wropt in mystery," but that these colours are now accepted as correct cannot be denied. Dr. Blochmann, in the current number of "Das Atelier," explains his choice of these colours, on the ground that they are the easiest to obtain, are the cheapest, and that the diffused light they give tends to softness of results. When these colours were chosen wet plates were the only sensitive material, and when dry plates were introduced they were only sensitive to blue and violet. Of late

filter. A similar result is obtained if we illuminate an object by blue or yellow rays. In Fig. 1 we have a blue and yellow chart, which in white light will look blue at the top, because this part absorbs all the rays in white light but blue. The lower part will appear yellow, because it only reflects the yellow rays.

If now this chart is illuminated by monochromatic light, such as blue, which is completely absorbed by the yellow, then this half must appear dark, even with the best ortho plate. If we take the same chart and illuminate it with pure yellow light, the effect is the reverse, for the blue half will absorb the whole of the yellow

years, especially for costume studies, orthochromatic plates have become more and more general. Professionals lay greater value on these plates, not only because the colours of dresses are better rendered, but because in other cases, as in light hair, dark blue dresses and yellow embroidery, a rendering more nearly like that seen by eyes is obtained.

What would be the result if we were to use a blue screen or filter? The orthochromatic action of the plates is destroyed, because the yellow rays do not reach the plate, as they would be absorbed by the blue

rays and appear dark, and the yellow part appear light, as shown in Fig. 3. In such a case an ordinary plate would be useless, but an orthochromatic plate useful.

The dark blue blinds in the studio have, to a certain extent, the same effect as monochromatic blue illumination. If they do not absorb all the yellow rays of white light, they still absorb a greater portion, and give a blueish illumination to the object, which does not give the best results on an orthochromatic plate. If, on the other hand, yellow or orange-coloured curtains were used, the full effect of the ortho plate would be felt, or, at any rate, a lighter yellow screen be required. Experiments in this direction are advisable, and orthochromatic plates ought to be more generally used in all studios.

PARAGRAPH which we notice in an Aberdeen paper to the effect that in the window of Mr. James Henderson, photographic dealer, is to be seen a good example of moonlight photography, having for its

subject the entrance to Aberdeen harbour, should be a reminder to our readers of the opportunities for minor advertisement which may often be embraced in the ordinary course of business.

## Exhibitions.

### DERBY CORPORATION.

IN February, 1886, just twenty years ago, the Corporation of Derby first housed in their Art Gallery a collection of photographs, the work of local amateurs, and, triennially, since then the same hospitality has been extended with ungrudging liberality, for the Corporation have not only undertaken, through their truly indefatigable curator, Mr. W. Crowther, the whole trouble and expense of organization, but have provided the medals awarded, and have offered unusual inducements to outsiders to exhibit in the open classes. Their leading idea is, however, to further the pursuit of photography by local men and women, and the one condition laid down is, therefore, that members of the Derby society shall respond by sending in their prints. On this is dependent the continuance of the exhibitions, and the success of this, the latest of the series, is a matter with which there is good reason to believe the Art Gallery Committee is amply satisfied, and on which the Derby Society and its more prominent officers, Mr. E. Collier Green, Mr. A. H. Bennett, and Mr. T. H. Thorpe are to be congratulated.

Two hundred and ninety-eight exhibits are hung, of which one hundred and eighty-five are in the local section, and a departure from the usual course is, that although the prints were judged in classes (four in each of the two sections), neither on the walls nor in the catalogue are they ordered according to classes, an arrangement confusing as regards appreciation of the awards, but which, of course, greatly adds to the pictorial effect of the exhibition. In the open section the Platinotype Company are represented by six large and very beautifully worked portraits, not for competition. Messrs. Alfred Ellis and Walery show several portraits of a theatrical as well as pictorial interest, notably, (79) "George Alexander as Francois Villon," and (70) "Stage Group in 'Sunday.'" Among the competing pictures Fred Judge has several landscapes of character; (96) "Glory," in which a telling landscape is subordinated to a sky effect which a less experienced worker might have made theatrical, and (17) "September." True in its unaffected charm is (2) "Evening after Rain," by W. H. Fowkes, and the same worker's (56) "Morning Gossip," a Dutch scene with figures and boats is decoratively designed. William Clayden's (45) "Tugging Home," has admirable qualities of atmosphere, delicacies of tone, and beauties of lighting, but the critic may grumble that the beams of timber uniting the boats in the foreground can hardly be called picturesque. The best of the Rev. C. F. Lowry Barnwell's exhibits is (6) "The Passing Storm," an effective, if sombre representation, of maritime grandeur. In A. R. F. Evershed's (12) "The Crane-November," a girder crane is cleverly balanced by a jet of steam, his portrait (111) "Study in Red," is a quite commendable effort in gum gone wrong, and (110) "Sunlit Sails," is a bold subject requiring more concentration of lighting. Miss A. B. Warburg's (95): "Three Fishers Went Sailing," etc., is dainty and audacious. From the flimsiest of materials—sea, spots of light, and three half-mysterious boats—this lady has made a notable thing. William Rawlins shows marked richness in the deep tones of (75), "On the Suffolk Marshes," but with just a suspicion of hardness, and in (40), "A Celtic Bridge, Dartmoor," he has a fine subject, the swirl of the water being livingly rendered and the distance fine, but a dominating idea has been missed and, perhaps, some concentration of the light on the water may merit consideration to this end. Frank E. Huson shows (74), "At Evening, When the Day is Done," and (35) "Thames Side at Chelsea," both of these subjects requiring the seeing eye, but the high-light is a trifle too insistent in each.

W. Croke sends fine examples of portraiture, including (62) "The Late Sir Henry Irving," but his work is so well-known to our readers that there is no necessity to remind them of its quality. Miss Marian Silverston has three or four good head studies, notably (22) "Onora," rendered with delightful reticence. E. O. Hoppé is a worker possessing original ideas, but in (18) "The Burden of Age," the position of the old man's hands gives a strange appearance to the picture. S. G. Kimber thrusts the sentiment at the spectator in (44), "Until the Day Breaks," through otherwise faultlessly and feelingly carried out, and skill is likewise exemplified in (101), "A Sunlit Clerestory," the features of which, however, seem to lack a supporting mass. (107),

"An Abode of Ancient Peace," by W. A. Clark, is full of real light, and (104), "A Flood of Light," also tells its tales reservedly and well. In F. Fleming's (92), "An Old Gateway," there is palpable evidence of mad use of a paint-brush, and Harold Hoare's (100), "Exeter Cathedral, from High Altar," gains no charm by being so dimensionally big. E. Seymour shows a number of very skilfully rendered fruit and flower subjects, and (99), "Japanese Anemones," by Dan Dunlop, pleasing, delicate, decorative arrangement, and not more. The blooms are lay figures, exquisitely perfect, but with none of the vitality of life.

Reference has previously been made to the good quality of the exhibits of the local workers, but we would suggest that putting more than one picture in a frame is usually harmful to each, and that where engraving effects are aimed at, the white margins should be of sufficiently ample dimensions. In this section are a number of pictures not for competition, notably a portrait of the King, (135), by W. W. Winter, who also shows (205), "The Duke of Devonshire," some worthy platinotype reproductions of the old masters, by Richard Keene, Ltd., and exhibits by W. R. Bland. Frank Cooper competes with prints of considerable power. (132), "Hengistbury Head," is effective but rather marred by the dark ridge of the headland coming strong and hard against the highest light of the sky, whilst the foreground of shingle would gain greatly by simplification. (179), "A Moorland Road," very narrowly misses prodigious strength and excellence. It is a desolate and characteristic moorland scene with a dark figure placed at the psychological moment, a remarkable achievement—but, a nearer examination shows the figure to be that of a young girl, so young that she wears her hair down her back, and a short frock. This, then, tells against the spirit of the scene; it suggests that the place is not half as bad as it looks; a strenuous figure was wanted. G. A. Fowkes has a decorative arrangement in (136) "Reflections, Rotterdam," and technique is shown in his (116) "Maartze," a portrait of a smiling Dutch girl. (142), "Alpsee," the work of G. Trevelyan Lee, is quite good in its tonality and its delicately rendered reeds, and would be even improved if the lighting of the distant waters were made more subservient to the reflections in the foreground. Douglas Deeley's (123) "Moors by Moonlight," is too heavy, but there is luminosity in the lighting of (221) "The Brook," and (150) "Apollo's Upward Fire," shows an insight into the moods of Nature which stamps it with personality. The distant hills in C. M. Etches's (134) "Swiss Alp," are mellow and true in tone, and the same worker is also represented in the architectural class by (264), "The Back Stairs," a quaint little peep. One cannot help feeling that Haddon Hall looms too largely in the architectural class, and is hackneyed. Derby men should have more respect for Haddon and for themselves than to continue to produce and to show selections from it which have been produced and shown until hoary with age. The case is different and wholly praiseworthy when a man goes there and says an old thing in a new or even in an unaccustomed way, and this has been done by C. H. Eaton in (249) "Haddon From the Terrace," by G. W. Riste in (169) "Corner in the Banqueting Hall," and by Mrs. E. Christine Allen (271) "Dining Hall," and this last one, too, in the Novices' Class. J. B. Copeland's numerous views of Haddon are of rich quality, and his (176) "Meditation," a portrait, is striking, but hard. E. Collier Green shows useful work in (211), "Yarmouth, Isle of Wight," and (119) "Whitby," and Captain A. J. Savage, R.E., in (236), "Boston Stump," has dignity and sunny atmosphere.

Dr. Vaudrey's best exhibit is (211) "Two Members of the Hatter's Brigade." We think this comes to the top with the cream of the show. Its simplicity and certainty are delightful. Simply, two girls in white, walking along a light-coloured, gracefully curving causeway. The deep tone of their hair (it is a back view) gives strength to the conception, and a subtle contribution to its success is its slight differentiation in the two dark spots these heads make. The only defects that one can find are, perhaps, the placing of the two small distant figures: certainly, that they are too dark in tone. J. C. Lee's (196), "Elsie," is a good rendering of flesh tones in shadow, and his (265), "A Milkmaid," is also excellent photographic work, albeit the maid, though good-looking, is somewhat stolid in expression. We are obliged to pass unnoticed the exhibits of several good workers. Some very promising work is shown in the Novices' Class. Mention has already been made of Mrs. Allen, and here we add T. H. Thorpe, who has overcome great difficulties

ities in (173) "The Potter." As the visitor leaves the room he will see over the door a large specimen of the work of that veteran photographer, T. A. Scotton, (297), "Midland Railway Compound Engine," a success as great as the print is immense. The judges in the open classes were Mr. F. M. Sutcliffe and Mr. C. Barrow Keene, and the local classes Mr. F. M. Sutcliffe, solus.

The following is the list of awards:—

**OPEN CLASSES:**—Landscape and Seascape: Silver medal, No. 96 (Jury), Fred H. Judge; Bronze, No. 6 (Passing Storm), Rev. C. F. L. Arnwell, and No. 74 (At Evening, When the Day is Done), Frank E. Benson. Portraits and figure studies:—Silver medal, No. 62, (The Sir Henry Irving), W. Crooke; Bronze, No. 22, (Onora), Miss Marian Silverston. Architecture:—Silver medal, No. 107, (An Abode of Ancient Peace), W. A. Clark; Bronze, No. 101, (A Sunlit Clerestory), S. G. Kimber. Flower Studies, Still Life, Etc.:—Bronze medal, No. 99 (Japanese Anemones), Dan Dunlop.

**LOCAL CLASSES:**—Landscape and Seascape: Silver medal, No. 132, (Langstbury Head), Frank Cooper; Bronze, No. 142, (Alpsee), G. Evelyn Lee; Certificate and Derby Society's Plaque, No. 150, (Dunlop's Upward Fire), D. Deeley. Portraits, Figures, Flowers, Etc.:—Silver medal, No. 265, (A Milkmaid), J. C. Lee; Bronze, No. 266, (Two Members of Hatless Brigade), Dr. Vaudrey; Certificate and Derby Society's Plaque, No. 116, (Maartze), G. A. Fowkes. Architecture:—Silver medal, No. 264, (The Back Stairs), C. E. Etches; Bronze, No. 236, (Boston Stump), Captain A. J. Savage, R.E. Novels:—Silver medal, No. 271 (Dining Hall, Haddon), Mrs. E. Christine; Bronze, No. 173 (The Potter), T. H. Thorpe.

#### DOVER INSTITUTE PHOTOGRAPHIC SOCIETY.

The third annual exhibition of this society was held on Wednesday and Thursday of last week. The following awards were made in the open classes by the Rev. F. C. Lambert, M.A.

**Landscape, Etc.**—1st, "Eventide," carbon, J. E. Latham; 2nd, "October," carbon, F. Judge; highly commended, "On Lago Maggiore," carbon, J. E. Latham. **Architecture, Etc.**—1st, "Until the Day Breaks," carbon, S. G. Kimber; highly commended, "Through Norman Arch," bromide, R. Somerford. **Portraiture, Etc.**—1st, "Oppy," bromide, H. Layland; 2nd, "A Study," carbon, E. Seymour; highly commended, "Le Masque," platinol, E. O. Hoppé. **Lantern Slides** (selected slide out of a set of four)—1st, "Mother's Day," Rev. H. Wright Dick; 2nd, "Poppies," E. Seymour; highly commended, "A Break, Etc.," F. J. Tryhorn; highly commended, "Norman Doorway," E. G. Amos.

#### NORWICH PHOTOGRAPHIC SOCIETY.

The following are the awards in the Open Classes at the third annual exhibition held by the Norwich Photographic Society:—

**Class 1.**—Landscape, Seascape, and River Scenery—S, "A November Morning," platinum, S. G. Kimber; B, "Sunrise, Boston," bromide, J. Ed. Hackford. **Class 2.**—Portraiture, Figure Studies, and Animals—S, "Beyond," platinum, D. J. Scott; B, "Cooling the Fire-hoop," bromide, R. Dixey. **Class 3.**—Architecture, Exterior and Interior—S, "Morning Gleams, Norwich," bromide, Alex. G. Benson; B, "A Sunlit Clerestory," S. G. Kimber. **Class 4.**—General Subjects—Flowers, Fruit, Still Life, Etc.—S, "A Study," E. Seymour; B, "A Study of Texture," P.O.P., luna, Henry W. Chapman. **Class 5.**—Lantern Slides—Sets of Four (any subject)—S, one set, "Life from Life," Francis Ward, M.D.; B, one set, 1 "Glory," October, 3 "The Old Parish Church," 4 "To Rest," Fred Judge.

#### MOTHERWELL CAMERA CLUB.

The fourth exhibition of the Motherwell Camera Club was held last week, when the following awards were made in the Open Classes:—Landscape and Seascape (Silver plaque), Dan Dunlop, Motherwell; bronze plaque, George L. Brown, Hamilton. **Portraiture and figure studies** (silver plaque), Dan Dunlop; bronze plaques, Miss Marion Woods, London, and W. H. Lindsay, Lowers, Hamilton. **Architecture** (silver plaque), William A. Clarke, Birmingham; bronze, plaque, James Dunlop, Motherwell. **Flowers and animal studies** (silver plaques), Dan Dunlop, and Robert Burnie, Glasgow. **Lantern slides, set of four** (silver plaques), H. McLeighton, Leicester, and Robert Burnie; bronze plaque, Henry Dick, Manchester.

#### FORTHCOMING EXHIBITIONS.

February-March, 1906.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

February 20-21, 1906.—Royal Albert Institute, Windsor. J. W. Gooch, Hon. Secretary.

February 22-24, 1906.—Bowes Park and District. Hon. Secretary, H. C. Bird, 91, Whittington Road, Bowes Park, N.

February 24—March 10, 1906.—Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 3A, N. St. David Street, Edinburgh.

February 24 to March 31, 1906.—Birmingham Photographic Society. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March, 1906.—Leicester and Leicestershire Photographic Society. Hon. Secretary, W. B. Woodland, 18, Beckingham Road, Leicester.

March, 1906.—Rugby Photographic Society. Hon. Secretary, R. N. Myers, 13, Bridget Street, Rugby.

March, 1906.—Photographic Society of Ireland. Hon. Secretary, H. V. Yeo, 194, Clonliffe Road, Drumcondra, Dublin.

March 5, 1906.—St. Helens Camera Club. Hon. Secretary, John Glover, 14, Ormskirk Street, St. Helens.

March 1 to 15.—Exhibition of work with anachromatic lenses, Photo-Club de Paris, 44, Rue des Mathurins. Secretary, Paul Bourgeois.

March 3-10, 1906.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 7-8, 1906.—Doncaster Camera Club. Hon. Secretary, T. Haigh Connor, 39, Market Place, Doncaster.

March 12-15, 1906.—Cripplegate Photographic Society. Secretary, John B. Parnham, 5, Reighton Road, Upper Clapton, N.E.

March 13-14, 1906.—G.E.R. Mechanics' Institute (Stratford). Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone, E.

March 14-17, 1906.—Nottingham Camera Club. Hon. Secretary, S. W. Barlow Yines, Market Chambers, South Parade, Nottingham.

March 19-24, 1906.—Sunderland Photographic Association. Hon. Secretary, William E. Kieffer, Stirling Street, Sunderland.

March 27, 1906.—Brentford Photographic Society. Entries close March 9. Secretary, Oliver Gluyas, 89, Windmill Road, Brentford, Middlesex.

March 31 to April 10.—Salon of the Photo Club of Nice. Address the Secrétaire-Général, 20, Rue St. Francois de Paule, Nice.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

April 2 to 7.—Photographic Society of Ireland. Secretary, W. F. Cooper, 194, Clonliffe Road, Drumcondra, Dublin.

April 18 to 20.—Southend-on-Sea exhibition. Hon. Sec., J. Archer, 24, Ashburnham Road.

April 18 to 21.—Bolton Amateur Photographic Society. Secretary, T. W. Croos, 27, Latham Street, Bolton.

April 20-21, 1906.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

May, 1906.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

APROPOS of the motto of the "New York Times," that it gives "all the news that's fit to print," a good story is told in the "Photographer." Mr. Eduard Steichen was being asked for some picture suitable for reproduction in the "Times" illustrated supplement. "He fetched out some lovely things which I was afraid would not reproduce well. Then he brought out a beautiful print, the eternal feminine, of course, but entirely separated from any semblance of wardrobe. Regretfully I shook my head as I thought of the family circulation, and then Mr. Steichen said: 'But you wanted these for the "Times," and I thought the motto of that paper was, "All the nudes that's fit to print!"'

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between February 5 and 10:—

**CINEMATOGRAPHS.**—No. 2,775. Improvements in mechanism employed in the production of cinematograph or multiscope pictures, and dark-slide for carrying sensitive photographic plates for taking impressions. William Henry Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London.

**CAMERAS.**—No. 2,931. Improvements in photographic cameras. Herbert William Jagger, 19, John William Street, Huddersfield.

**PRINTING APPARATUS.**—No. 3,067. Improvements in photographic printing apparatus. Joseph Halden, 17, St. Ann's Square, Manchester.

**ARTIFICIAL LIGHT.**—No. 3,128. Illuminating apparatus for photographic purposes. Marwood Short, 37, Chancery Lane, London.

**CINEMATOGRAPHS.**—No. 3,198. Improvements in cinematographs and attachments thereto. W. P. Thompson, 6, Lord Street, Liverpool, for William Henry Baker, United States.

**REFLEX CAMERAS.**—No. 3,324. Improvements in photographic cameras of the reflector type. Walter Dockree, Valentine William Edwards, and Houghtons, Ltd., 88-89, High Holborn, London.

**DEVELOPING APPARATUS.**—No. 3,342. Improvements in apparatus for developing photographic plates. Sydney Arnold Atkinson, Birkbeck Bank Chambers, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**COOKE LENSES.**—No. 3,398, 1905. The invention has for its object the modification of the Cooke lens so that the separate parts may be used as lenses of twice or thrice the focal length of the complete lens—or other multiple of the whole lens. The claims are:—1. A triple or quadruple Cooke lens, having the power of its negative lens, or the sum of the powers of its two negative lenses, approximately equal to the sum of the powers of the two (modified) positive lenses, so that it can be used either singly or conjointly with a similarly modified lens of equal or unequal focal length. 2. The conjoint use of Cooke lenses already existing such as the one described herein as Series V, any two of such being joined together as in Fig. 2, with a stop between them, and their focal lengths being equal or unequal. Fig. 1 shows a section of the series V Cooke lens, which, as it stands, is more suited than any other of them for conjoint use, although it requires modifica-

Fig. 1.

tion. At present the diaphragm is situated close behind the negative lens at D—D, but for conjoint use the diaphragm has to be transferred to the front of the front lens  $L_1$ , as shown at  $d-d$ . But that position is so much further from the back lens  $L_4$ , that pencils of light of a moderate degree of obliquity cannot get through the combination, but strike outside of the aperture of the back lens. Therefore, the modification that is, as a rule, required is to get the whole combination shortened up along the optic axis so as to get the aperture of the back lens to subtend a larger angle as viewed from the centre of the front stop. That being attained, then two such front stop lenses of equal or unequal focal lengths, may be placed together as in Fig. 2, stop to stop:

one stop then acting in common. Thus the whole combination will yield a very powerful lens of large aperture, while either half, used preferably with the stop end towards distant objects, will perform as a self-contained and perfect lens of a longer focal length. The attainment of a three-lens combination like Fig. 3, short enough for such conjoint use implies that the positive lens  $L_1$  or the one most remote from the diaphragm shall be of a very much longer focal length than the other one  $L_4$ . But such a condition, however well adapted it may be for wide angle combinations, is yet not the most suitable if the largest possible working aperture is to be attained. In order to obtain the largest positive relative aperture I must be about equal power to  $L_4$ , but in order to get the spherical aberration balanced in such a case it is absolutely necessary to divide the negative lens into two parts or lenses of equal or unequal power. Fig. 3 is a sketch of such a combination as roughly calculated

Fig. 3.

out, whereby it is hoped finally to get an aperture of  $f/7$  and of  $f/35$  when two such constructions of equal focal length are used conjointly. In all the combinations suggested above it is necessary in order to obtain a flat final image substantially free from astigmatism, to embody the principle which formed the basis of the Cooke lenses (Patent No. 22,607, 1893), viz., that the sum of the powers of the negative lenses employed must be approximately equal to the sum of the powers of the positive lenses; a large part of the power of the combinations being the sole result of the separations between the component lenses. For instance, and especially if the refractive indices of the glass used for the negative lenses be equal to the refractive index of the glass used for the positive lenses, the sum of the power of the negative lenses may be exactly equal to the sum of the powers of the positive lenses, and yet there results a considerable power for the combination owing to the separations; the greater is the excess of the refractive index of the positive lenses over that for the negative lenses the more may the relative power of the negative lenses be legitimately relaxed. Even if the refractive index of the negative lenses is in excess compared to that for the positive lenses, yet the power of the negative lenses even then need not be quite equal to the powers of the positive lenses, but the fulfilment of the former of these opposing conditions is highly desirable, and so long as the combinations are kept as short as possible along the axis there will be little difficulty in employing dense barium crown glass of a refractive index of about 1.61 for the positive lenses and a very light flint glass or highly dispersive crown glass of refractive index of from 1.53 to 1.57 for the negative lenses. These constructions can also be used for lantern projection and as microscope objectives.

The specification gives the curves and other data for a special Cooke lens to be used conjointly. Harold Dennis Taylor, Stancliffe, Mount Villas, York.

An enlargement competition has been instituted by Messrs. Burroughs and Wellcome; prizes from one to five guineas are offered for the best enlargements made with "Tabloid" metol-hydroquinone developer. The competition closes May 28 for Great Britain, on April 16 for Australia, and on May 7 for South Africa.

A SAMPLE portfolio of postcards reaches us from Mr. Philip Hunt, 100, Deansgate, Manchester, who draws our attention to the special lines handled by him for professional photographers undertaking the publication of local postcard views.

## New Apparatus, &c.

the Wellington Light-filter. Made by Wellington and Ward, Elstree, Herts.

When, at about this time last year, we reviewed the new Wellington "Iso Speedy" plate, we took occasion to point out the very high orthochromatic ratio which it possessed. The figure expressing at ratio was 1.75, that is to say, the proportion of blue sensitiveness to yellow sensitiveness, according to the definition of Mr. C. E. Kees, is expressed by this figure, and those who have studied values of this kind will bear us out that it represents an intense colour-sensitiveness. This (relatively) low blue-sensitiveness, to put the matter another way, calls for a light-filter of small absorptive power,

such we find the present filter to be. The makers call it a "ve-times" screen, a nomination which, without explanation, does say very much. We assume from the exposures we have made through the screen on "Iso Speedy" plates, that the filter gives good colour rendering with this increase of the normal exposure. Optical working appears to be excellent, and it is placed on the market conveniently ensconced in a leather case. The light-filter made in two sizes, No. 1, for lenses from 1 inch to 1½ inch diameter, and No. 2, for lenses from 1½ inch to 1¾ inch. The former costs 1.6d., and the latter 12s. 6d.

"Carl Norman" Proportion Measure. Sold by Messrs. A. W. Penrose and Co., 109, Farringdon Road, London, E.C.

By the simple device of an elastic graduated measure, Mr. Carl Norman has enabled all those ordering half-tone blocks to ascertain once the length any given original will assume in one direction when a certain enlarged or reduced length is fixed upon for the order. An example will explain how it is used. We desire, suppose, to reduce a 15 by 12 print to 6in. across the 15in. side. What will the length of the 12in. side in the block. We lay the measure across the print and stretch it until the 15in. measure 6in. on the elastic. With the measure at the same tension we then at once read the length of the 12in. side—viz., 4½in. A scale on the reverse of the measure permits of enlargement calculations being made in the same expeditious manner, and should be equally useful to photographic enlargers. The price of the proportion measure is 4s.

"Allways" Rapid Postcard Printing Frame. Made by W. L. Parkinson, Ltd., 62, Dale Street, Liverpool.

This frame presents some distinctly new features, which will considerably facilitate double printing, and also enable one to obtain series of prints or postcards from any part of a negative, and exactly alike. The front of the frame slides apart, so that any negative, from the smallest to whole plate, can be used. The frame is provided with a slotted sliding piece, which can be clamped

in any desired position, and thus forms a setting gauge which enables exact register to be obtained for double or triple printing. The frame should be extremely useful for those processes of colour photography in which accurate superposition of negatives and prints

is required, as when once the negative is placed in position, a clamping screw locks the sliding back, the sliding rails and the negative. The price of the frame is 2s.

## New Materials.

Chrom-Colloidon Emulsion. Made and sold by Stephen Tallon, 2, Francemary Street, Ladywell, London, S.E.

A sample of a new colloidon emulsion specially supplied for process-work, and especially for direct screen-negative making, has been submitted to us by Mr. Tallon, at whose request we have subjected it to a thorough practical test of its suitability for photo-mechanical purposes. As such test is inevitably a comparative one, our experiments were made in comparison with a commercial ready-made emulsion, and as a result we must say that so far as our observations went, the Tallon product proved in every respect its superior. It was found to be slightly faster, it gave negatives of much greater contrast, density was easily obtained without fog, and the emulsion supplied negatives with clean dots. The emulsion readily takes the special eoside colour-sensitising dye supplied with it, and we also find it to be easily amenable to the new isocyanines. If the bulk of the supplies are equal to the sample we shall not be surprised to find photo-engravers and other process men placing very considerable orders with the maker. The emulsion is supplied in 10, 20, and 40 ounce bottles, in each case with a separate solution of eoside sensitiser for use in making the green-screen negative. For the red-screen negative Mr. Tallon recognises the favour in which ethyl violet is held by process operators, and recommends its adoption in connection with his emulsion. The price of the emulsion is 7s. 6d. per 10 ounce bottle, and the following brief hints are advanced by the maker for the guidance of those using it for the first time:— 1. Shake well before use, then add the dye (eosin-silver) in proportion of one part of dye to ten parts of emulsion. 2. Do not dye more emulsion than is required for the day's use. 3. Warm the developer slightly in cold weather. 4. When making screen negatives use the special bromide solution; this ensures greater sharpness of the dots. 5. Develop fully, then wash and fix with cyanide or hypo.

POPULAR Photographic Literature.—The sixpenny textbook having recently obtained a footing in the photographic publishing trade, it is interesting to hear that a war of cut prices is shortly to be witnessed in the issue of manuals on photography at 4d. each, by a firm which has led the way in popular text books of the practical kind. It is not easy to understand how such a price can leave a margin of profit, but possibly the enterprise is prompted by motives of advertisement.

THE Civil Service Motor and Cycle Agency, Limited, in which is included the Service Photographic Society, will in future be known as the Service Company, Limited, the new title having been adopted to secure brevity and also to cover the various branches of the business.

## CATALOGUES AND TRADE NOTICES.

TECHNICAL advice and instruction in the important branches of professional photography being frequently sought by our readers through the medium of our columns, it may be well to draw attention to one source of supply, the value of which we have had frequent opportunities of observing. Mr. T. S. Bruce, of 4, Villas-on-Heath, Vale, Hampstead, in collaboration with three expert associates, has proved himself progressive both in the tuition of beginners and in the improvement of practised workers. His arrangements include instruction in black and white and water-colour finishing by a leading worker for West-End studios, in miniature painting and tinting by a Royal Academy medallist, and in studio erection and operating by an architect and professional photographer. Retouching in all its branches is Mr. Bruce's own subject, in the teaching of which, personally and by post, he has obtained a justly deserved and acknowledged success. Perhaps that success has been due as much to the fact that Mr. Bruce has studied the individual needs of all classes of professional retouchers as to his careful training of the beginner. There is retouching *and* retouching, and many a worker who imagines he has nothing more to learn, would surprise himself, and incidentally improve his position, by following up his early lessons in his special line, or in one of the allied branches of the retoucher's art.

A NEW booklet of the Telephoto Cornex camera has been issued by Messrs. R. and J. Beck, 68, Cornhill, London, E.C., in which are reproduced some fifteen examples of the use of the camera from negatives made by a user on the first occasion of handling. In most cases the illustrations are comparative examples showing the effective use which can be made of camera in photographing from distant standpoints. For this reason the list is one which the photographic tourist might peruse with profit.

A CIRCULAR from the Aerograph Company, 43, Holborn Viaduct, informs us that a reduction in the prices of Aerograph machines comes into force during the current month, and, subject to increased sales, is to be permanent. The A pattern instrument previously sold at £7 7s. is offered at £5 10s., and the reduction on other apparatus is in a similar proportion.

AN advance list of hand-cameras for the coming season has been issued by the Tella Camera Company, pending the appearance of the company's full catalogue at the end of March. The list specifies some popular varieties of hand and stand cameras, and is sent free from 110, Shaftesbury Avenue, W.

MESSRS. Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C., send us their latest price-list of photographic chemicals and apparatus, among the latter being the new Agfa dark slide for daylight-changing films.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
23.....	Colne Camera Club .....	Photographic News Prize Slides.

BURTON ARCHAEOLOGICAL SOCIETY (PHOTOGRAPHIC SECTION).—paper was given last week by Mr. F. W. Bidie, who spoke on colour photography, describing in detail many of the present processes which, he said, was termed colour-photography for the want of better name, as, in his opinion, there was no so-called process before the public. All examples were now coloured photographs, as they could not, with reason, distinguish between a print with colour flooded on in a bath, to one with colour placed on by hand. The only exception was, perhaps, the Lippmann process, which was distinguished

from all others, being essentially an interference process. It consisted of a mirror of metallic mercury placed behind the plate, which was developed and fixed in the ordinary way. The result had to be viewed at a certain angle, and this destroyed all chance of it ever being a commercial success, and it remained, as it did ten years ago, a curiosity, and nothing more. The lecturer remarked that Lumières had withdrawn their three-colour process from the market, and they would not have to wait long for an explanation. He also outlined the Sanger-Shepherd process. Both processes consisted of taking three separate negatives, under three distinct screens, staining the prints a complementary colour, and finally adjusting one over the other. In conclusion, he referred to the process where a photograph is taken through a screen ruled with alternate colour lines, and, after the ordinary manipulation, was seen in colour when viewed through a similarly-adjusted screen. This process was the simplest the amateur. A set of lantern slides, demonstrating the three-colour process, was exhibited.

**WARRINGTON PHOTOGRAPHIC SOCIETY.**—"Save your silver" was amongst the interesting items of a lecture delivered before the Warrington Photographic Society by Mr. J. S. Hill. With regard to this point, he said that a profitable investment for societies would be an old barrel into which exhausted hypo bath should be added. The barrel being filled, add to each six gallons of its contents half pound sulphuretted potash (live of sulphur) previously dissolved in a pint of hot water. Having stirred the whole well together and allowed to rest, the silver will separate and settle in the form of sulphide of silver. Eight inches from the bottom of the barrel bore a hole in which a plug-tap must be inserted, through which the liquid, which should be quite clear, can be allowed to run to the drain. Now collect the muddy precipitate from the bottom, and wash with several changes of water to free the silver white from impurities. Having obtained this, it may be turned to various uses, i.e., sent to the refiners as it is, or, the sulphur burned off it by heating on hot iron-plates or in an old pan, thus leaving it is practically metallic silver in a finely divided state, or another way would be to put the sulphide of silver in nitric acid, thus dissolving out the silver in the form of nitrate of silver, which is the more liquid. This can be evaporated and crystals of nitrate of silver obtained.

**ROTHAMPTON CAMERA CLUB.**—In the Club Lecturette Competition on Monday, the 19th inst., Mr. A. F. Gibbings took first place for "A Holiday in Saxony," while Mr. C. M. Cooper was second for "Denizens of Lane and Wood."

**HACKNEY PHOTOGRAPHIC SOCIETY.**—The annual dinner of this society took place on Tuesday last, February 20, at the Great Eastern Hotel, Liverpool Street, under the chairmanship of Mr. Harold Webb, President of the Society. Members and friends, numbering nearly one hundred, sat down to dinner, and the whole proceedings were volumes for the continued prosperity and activity of the society. Among the guests were Mr. H. Snowden Ward, Mr. H. W. Bennett, Rev. F. C. Lambert, Mr. A. Horsley Hinton, Mr. F. J. Mortimer, Mr. George E. Brown. The toast list formed a pleasant souvenir on the occasion in the form of a photographic reproduction of a piece of pictorial photography of the President. After the honouring the Royal toasts, "The Hackney Photographic Society" was proposed by Mr. Horsley Hinton, who referred to the uninterrupted prosperity of the society, and associated with that success the name of the tireless secretary, Mr. Walter Selfe. Mr. A. J. Linford referred for the society. The health of the President was proposed by Mr. Wm. Rawlings, who presented to Mr. Lane an album of photographs contributed by members, and referred in terms of appreciation to the tact, energy, and versatility which Mr. Lane had brought to his duties of his office. The Chairman, in responding, expressed the sure he had had in the hearty support of the members during his tenure of office, and spoke of the firm friends which it was his privilege to number among the members of the Hackney Photographic Society. An excellent musical programme contributed to an altogether enjoyable evening.

**WARRINGTON PHOTOGRAPHIC CLUB.**—In the course of an interesting lantern lecture describing his tour round the world, given to his fellow-members on 16th inst., Mr. J. C. Marshall stated that his results were obtained on roll film, the spools of which, both before and after

exposure, were each stored in its own air-tight tin case. To give some idea of the trying atmospheric conditions met with, he stated that he put some cut films in double backs, which were packed in a stout leather case; this was kept in a tin cabin trunk, which was protected by being placed in an apparently dry locker in the cabin. On arriving at Ceylon and examining the films, they were found to be drawn or rolled up into a shapeless mass of gelatine and celluloid. The camera he used throughout his trip was "Lizar's Challenge Dayspool," which came out of the ordeal little the worse for its tropical environments. He advised others who might be doing a similar round to take their own supplies, as, apart from the difficulty occasionally met with in replenishing, in most instances, particularly in protected countries, there was a very considerable increase in the prices charged. On the other hand, there was just a risk that the amateur might be called upon to pay duty upon his supply of films or plates.

**CHELSEA PHOTOGRAPHIC SOCIETY.**—The third Annual General Meeting was held on the 15th February. Messrs. F. Humpherson and J. H. Quinn were elected vice-presidents; Mr. F. Webb, hon. secretary; Mr. R. C. Gibbs, hon. treasurer; and Mr. J. G. Cooling, hon. lanternist. The committee reported a very successful year's working and a satisfactory condition of the Society.

## News and Notes.

**THE BIRMINGHAM EXHIBITION.** We hear that the exhibition of the Birmingham Photographic Society, which opens to-morrow (Saturday) will be quite a notable one in the show it will make of leading foreign pictorial photographers. It is expected that the representation of the foreign exhibitors will amount to 200 photographs, many very fine and some superb. Probably when the doors are opened to the public it will be found that Birmingham has this year added to its numerous successes the assemblage of as fine a collection of foreign pictorial work as has ever been seen in this country. Our readers who are able to visit the Midland capital while the exhibition remains open should not miss the chance which is thus offered to them. A review of the exhibition will appear in our columns next week.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Certain incidents at a recent function of the Royal Photographic Society to which allusion has been made in one of our contemporaries have apparently prompted the drafting and posting of additions to the Standing Orders which we print below. We do not propose to open our columns to the possible discussion of a matter which is very largely personal, and to which the Council of the Royal Photographic Society, it seems to us, have attached unnecessary importance. We can understand that certain indiscreet actions on the part of a non-member of the Society has been received with justifiable resentment, but the whole matter in our eyes appears too insignificant for us to enter into its details, and we are confident that we are consulting the wishes of the great majority of our readers in declining to admit the discussion of a subject which, so far as we can judge, does not possess the least public interest. The following are the additions to the Standing Orders referred to:—

No. 5.—No member shall introduce to the Society's house, as a visitor, any person who has been rejected on application for membership.

No. 12.—Smoking shall be permitted at practical demonstrations, at technical meetings, and at annual general meetings, but not at ordinary meetings nor at lantern meetings.

No. 14.—Morning dress only is requisite at meetings held in the Society's house, except when other arrangements are made by the Council.

**A POSTER for the R.P.S.**—The following are the conditions arranged by the Council of the R.P.S. for a competition for a suitable poster:—The Royal Photographic Society of Great Britain offer two prizes of five guineas and two guineas respectively for designs of a double-crown poster suitable for advertising the Society's annual exhibition.

The words "Photographic Exhibition" and "Royal Photographic Society" should be boldly displayed, although designs in which the positions of these words are only indicated and the words are not actually lettered will be eligible for competition. The designs must be for one or two colours and must be submitted in full size (30 by 20 inches). About three-fourths of the area may be occupied by the design, including the words quoted above, and a panel or panels occupying about one-fourth of the space must be left blank for letterpress. Other matters being equal, preference will be given to designs suggesting photography or the action of light. The competition will be judged by the Editor of "The Studio," in conjunction with a committee appointed by the Royal Photographic Society, and the prize drawings, together with the copyright therein, will become the exclusive property of the society. Drawings, carefully packed, to be received at the London office of "The Studio," 44, Leicester Square, by April 1.

**THE South London Exhibition.** We reproduce herewith a full-size facsimile of the plaques to be awarded at the forthcoming South London Exhibition, which opens on March 3, and closes on

the 10th. The exhibition, we understand, promises to equal its predecessors, and those able to attend it should obtain a programme of the attractions from the secretary, Mr. H. Creighton Beckett, 44, Edith Road, Peckham.

**BRISTOL Exhibition.**—The date of this exhibition has now been fixed for October 6 to 13, 1906, inclusive, and the following open classes have been decided upon—viz.:—(A) Champion class—open to all pictures which shall have been awarded a medal at any previous open exhibition. All medalled pictures entered in Classes B, C, D, E, and F (see below), as well as those awarded medals in these classes at this exhibition, will be entered in this class by the hon. secretary as a matter of course, and will thus stand a chance of gaining two awards. The awards will be a silver gilt plaque, a silver plaque, a bronze plaque, and a certificate. (B) Landscape, seascape, and river scenery. (C) Portraiture and figure studies. (D) Architecture. (E) Fruit, flowers, and still life. (F) Any other

subject. (G) Lantern slides. There will be awarded in each class, from B to G inclusive, a silver plaque, a bronze plaque, and a certificate. For further particulars apply to the hon. exhibition secretary, Mr. J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

**THE Zander Complementary Colour Process.**—The first lecture by Mr. C. G. Zander on his four-colour process will be delivered at the St. Bride Institute, Ludgate Hill, E.C., on March 7 at 7.30.

**ELECTRIC Light Demonstrations.**—The Boardman Electrical Patents Company, of 10, Southwark Bridge Road, announce that in the course of the next month or two they will be opening a demonstration studio in the West End of London, in which they will be able to show professional photographers the capabilities of their various types of arc lamp.

**THE Marble Arch.**—Mr. F. W. Speaight, photographer, of New Bond Street, who recently put forward a scheme for the improvement of the position of the Marble Arch, was recently received by Mr. Harcourt, First Commissioner of Works, to whom he explained the plans by which the congestion of traffic at the north-east corner of Hyde Park is to be relieved and a position given to the Marble Arch worthy of its architectural character. His suggestion is to set back the park railings and make a semi-circular space of 360ft. in diameter, in the middle of which would remain the Marble Arch. The arch would then be seen, serving no longer as a mere gateway, but standing apart, a magnificent monument. It would become a leading feature in the great Processional Road, which, starting from Trafalgar Square, proceeds through the Mall to the Victoria Memorial, thence to Constitution Hill and Hyde Park Corner, to the Arch. Mr. Speaight further proposes to call the noble sweep to be formed at the Marble Arch, "The Crescent of Peace," and that it be embellished with a suitable allegorical railing and screen, as well as permanent, ornate Venetian masts. Numbers of distinguished sculptors, painters, and architects, like Sir William Richmond, R.A., regard the proposal as admirable. Mr. Hamo Thornycroft, R.A., hopes it may be carried out, and Sir L. Alma-Tadema says it would alleviate the great congestion of traffic. The London County Council have not until now been approached collectively upon the subject, but many of the members are familiar with the scheme and approve of it. As they have recently visited Paris in a body, and it was the Arc de Triomphe's position that first put the matter in Mr. Speaight's head, he has forwarded printed papers about the improvement to each member. Mr. Harcourt is said to have entertained the scheme in a favourable, or, at any rate, kindly spirit. It is now officially before the Government and other authorities. If Mr. Harcourt approves he will doubtless call the attention of the proper persons to the matter, so that the suggested scheme may be carried out, and a great London thoroughfare made safer and easier, as well as rendered far more picturesque.

## Commercial & Legal Intelligence.

**BANKRUPTCY.**—John West, cycle dealer and photographer, of Atherton, was examined at the Bolton Bankruptcy Court, on Wednesday, when it was shown that he had a deficiency of £113 13s. 11d., his unsecured liabilities amounting to £133 6s. 7d., and assets £19 12s. 8d. He commenced business as a photographer without capital, but as there was a good deal of competition, his expenses were more than his income. He started to borrow money from moneylenders, and in that way his liabilities increased rapidly. He had known of his insolvency for two years, but had expected to do better. The examination was closed.

**ACTRESS'S Photographs.**—In the Chancery Division of the High Courts of Justice last week, before Mr. Justice Warrington, Mr. G. F. Hart applied for an interim injunction to restrain the Rotary Photographic Company from publishing and circulating picture postcards bearing the photograph of Miss Florence Smithson. The lady was, he said, an actress and singer in light comedy, who was now playing the principal part in the "Blue Moon," at the Lyric Theatre. In her affidavit she said that while singing at the Theatre Royal,

ter, some two years ago, she went to the studio of a Mr. Chandler the Arcade, and had her portraits taken in the characters of "Arlina" and "The Daughter of the Regiment." These were portraits which were now being reproduced by the defendant company, and she supposed that Mr. Chandler had sold the negative them. She objected to their action on the grounds, firstly, that photographs were old ones, and secondly, that she had given the right of reproduction to Messrs. Bassano. The statement of Mr. Chandler was untrue so far as it inferred that she sat for her photographs by invitation; they were ordered and taken in the ordinary way. Mr. Justice Warrington refused to grant an interim injunction but gave leave for short notice of motion.

**NEW COMPANIES.**—Hudson and Grousell, Limited, Capital, £100,000 in £1 shares. Object, to adopt an agreement with A. Hudson and G. W. Grousell, and to carry on the business as printers, photographers, stationers, bookbinders, etc. No initial public issue. The directors (to number not less than two nor more than five) are A. Hudson (managing director and chairman) and A. Hudson. Registered office: Priory Mews, Priory Grove, South Lambeth.

**ALLEGED False Pretences.**—Before the Bingley Petty Sessions last week a Bradford photographer, named Arthur Bradley, was charged with obtaining 2s. 6d. from a lady whose house he had apparently photographed, and from whom he had taken the amount as payment for a print to be supplied. The photograph had not been delivered, and the action. For the defence it was stated that the accused gave a good answer to the charge, and he was remanded on bail.

**PROPER POSTCARDS.**—At West London, last week, three Fulham shopkeepers—Francis Harris, newsagent, of Lillie Road; Thos. W. S., stationer, of Fulham Road; and Charlotte Raulin, confectioner, of Lillie Road—were prosecuted on summonses for exposing and selling picture postcards for sale. For the defence it was stated that the vendors were induced to buy the cards by a traveller for a resale firm, who assured them that the cards would "pass for real." The magistrate imposed a fine of £10, with three guineas, in each case, and ordered the cards to be destroyed. Raulin's shop was raided by Insp. Pettitt, was defended by Mr. Raulin, who suggested that the police ought to proceed against the resale firms whose innocent victims these small shopkeepers were. The magistrate imposed a fine of £5, with two guineas, in her case, and ordered the cards to be destroyed.

**COPYRIGHT CASE.**—An action relating to the copyright of picture postcards was heard by Judge Mansel Jones, at Sheffield County Court, on Friday. The plaintiff was Frank Mottershaw, who trades as the Sheffield Photo Co., at 95, Norfolk Street, and he sued Mr. P. Skelton, stationer, of City Road, for two guineas, the agreed upon for the reproduction of four pictorial postcards. Walpole Hiller conducted plaintiff's case, but defendant had no solicitor. The four views were taken by plaintiff, and produced copyrighted photograph postcards. Later he discovered that defendant had reproduced the pictures as cheap tinted cards. Then, as stated, defendant agreed to pay the usual reproduction fee of half a guinea for each copy. Now he denied entering into such an agreement, and contended that the fee was too large. His counsel held that there had been an agreement between the parties, and that the fee charged was reasonable. Judgment was, therefore, given for plaintiff.

**KNASSING FRAUD.**—A man who stated he was a canvasser in the employment of a portrait company, was remanded to Lucan Petty Sessions last week, on a charge of stealing a valuable pipe, the property of John Murphy, of Laracor.

**Art Photography.**—Before the Bournemouth City Court last week, Samuel Richard Rosenberg, of The Homestead, St. Peter's Street, Bournemouth, sought to recover from De Jornette Plummer, photographer, Bournemouth, the sum of £8 8s., damages for breach of contract and detention of goods. There was a counter claim for £5s., made up as follows: Money lent, £1; motor horn, 15s.; expenses sustained through plaintiff leaving, £8, also a claim for an action to prevent plaintiff acting as photographer locally. Mr. Tattersall appeared for plaintiff, and Mr. H. Trevelyan for the defendant. Mr. Tattersall stated that plaintiff was formerly in the employment of the defendant, and in November he entered into an agree-

ment with Mr. Plummer to become a photographer's assistant in the shop in St. Paul's Churchyard, London, where defendant was carrying on business. Afterwards it was arranged that plaintiff should go to Bournemouth and work in a shop which defendant had taken there. He remained in defendant's employ until a few months ago, when, notwithstanding the fact that the agreement provided for an engagement of three years or longer, Mr. Plummer summarily discontinued the employment of plaintiff. The latter therefore claimed one month's salary in lieu of notice. In addition, the plaintiff had a photograph and frame which defendant detained. The frame, however, had been returned, but not the photograph, valued at 4s., so that the total claim was thus limited to £8 4s. Plaintiff stated that the defendant told him on December 11 that his services were no longer required. Mr. Trevelyan contended that the plaintiff knew nothing of defendant's system until he met defendant. The defendant considered that, having taught the assistants this process, which he had in use in thirteen towns in the United Kingdom, he was entitled to bind plaintiff not to set up in any photographic business similar to that which he (the plaintiff) carried on. The defendant, who described himself as a rapid art photographer, said he possessed a patent for rapid art photography. When plaintiff came to him he knew nothing about photography, except re-touching, and on that account he was only paid 23s. per week. Witness used a special printing machine which no one else could use without his license. He also used special solutions for developing and washing; the printing was done by machinery. He did not know of any other system which could produce photographs so rapidly as his system. His Honour gave a verdict for plaintiff on the claim for £8. He thought there was an entire absence of proof that the plaintiff had infringed, worked, or used the defendant's process. Therefore he could not grant the injunction and would dismiss the counter claim altogether. With regard to the defendant, that decision in having refused the injunction would by no means enable the plaintiff to use the patent process.

### "Sanzol" AND SULPHIDE TONING.

To the Editors.

Gentlemen,—In Mr. Wall's very interesting article re "Sanzol," in your issue of the 2nd instant, he suggests that my experience of the action of cobaltamine compounds on the silver image might enable me to give an opinion as to the reason for the action of "Sanzol" on sulphide-toned bromide prints. The only explanation that I can offer is, that prints so toned often contain silver as well as the normal sulphide. The silver would, of course, be attacked by the "Sanzol," leaving the print much lighter in colour, the darker part of the image being dissolved, and the remaining normal silver sulphide, which has far less covering power, showing more of a yellow colour.

In view of the generally accepted stability of the sulphide-toned image, I am quite aware that such a suggestion will probably call forth some severe criticism, but I am myself thoroughly in agreement with your remarks in last week's editorial column, as to the frequent partial conversion only of the image into the normal sulphide.

No doubt many who are familiar with the bleaching, and sulphide toning, as applied to bromide prints, have at times noted that in applying the sulphiding solution, after bleaching and rinsing, the image that quickly appears is often at first nearly black, the continued application of the sulphiding solution changing the colour to the usual rich brown.

I have up to now been unable to determine what the nature of

this first almost black image may be. Perhaps Dr. Chesterman or Mr. Wall can help us on this point.

I at first thought that the black image was largely the silver hydrate described by Dr. von der Pfordten as always being produced mixed with silver, when silver salts are reduced, the excess of caustic alkali, nearly always present in the sulphiding solutions, leading me to think this possible.

I have since, however, thought that the image first formed is more likely to consist partly of a sub-sulphide of silver, such as the  $Ag_2S$  described by Guntz (Comptes Rendus 112, 861, 1891). This compound is no doubt as liable to break up into free silver and normal sulphide as the sub-chloride that Guntz prepared was to break up into free silver and the normal chloride.

The remedy, of course, is to give sulphide-toned prints a longer immersion in the sulphiding bath, though I hardly think that anything like a quarter of an hour is necessary for bleached bromide prints, though for P.O.P. prints it may, as Dr. Chesterman says, be advisable. At any rate with the bleacher that I always use, a full minute after the image is apparently fully up is sufficient, but it is just this extra minute that makes all the difference, and which, I fear, some people in a hurry dispense with. May I say, in conclusion, that I think Mr. Wall was rather unfortunate in getting blisters on P.O.P. prints when reducing with the normal "Sanzol" reducer, as I have reduced many kinds of such prints without any such trouble. The ammonia bath, however, must not be stronger than 3 per cent., nor should the prints be left in it longer than three minutes, which is quite long enough when nitric acid is used to acidify. If organic acids are used, however, a longer immersion in the ammonia bath is certainly often necessary to remove a yellow insoluble silver-cobaltamine compound which is apt to be troublesome in this case, and for this and other reasons I cannot recommend the use of organic acids for practical work.

Anyone, however, sufficiently interested to experiment in this direction would, I think, find oxalic acid one of the best to use, though not if the purple or bluish toning action is objected to, as I have found that oxalic acid generally shows this toning effect. I mentioned in some notes on the subject last May ("The Photographic Journal" 45, No. 5, p. 189) that I had been unable to determine whether this deposit was silver or cobalt, and I regret that I have not had time to go further into the matter since. The deposit is probably a mixture of both, the silver being brought into solution by the first part of the reducing action, and subsequently redeposited.—I am, gentlemen, yours faithfully,

H. E. SMITH.

Ezra Street, Columbia Road, London, E.

February 19, 1906.

#### NEGATIVES TAKEN IN THE GUIANA FOREST.

To the Editors.

Gentlemen,—We refer to the question asked by your correspondent, "Old Subscriber," on page 140 of your issue of the 16th inst., and would ask to be allowed to say that if your correspondent would care to send us the negatives mentioned, we should be happy to do our best for him.—Yours faithfully,

ILFORD, LIMITED.

Ilford, London, E., February 17, 1906.

#### TO PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—Will you allow me to suggest to the members of the numerous photographic societies who may be desirous of expressing their gratitude to their secretaries, who do so much for the enjoyment and instruction of their members, that the forthcoming Photographic Convention to be held at Southampton in July offers a capital opportunity of paying a compliment to their secretaries, and at the same time benefiting their societies.

There are often difficulties in giving a testimonial, but if each society would make its secretary a member of the Photographic Convention by the payment of the 5s. subscription, and pay his expenses for the week, it would be a pretty compliment to a hardworked official who could not fail to learn much from his association with all the leading photographers of the world, and would be able to

transmit that knowledge to his fellow members on his return.—Yours truly,

Blenheim Club, St. James's Square, London.

ERNEST J. HUMPHREY.

February 14, 1906.

[This suggestion from the President-elect of the Convention is obviously one of benefit to any society as to need no endorsement from us. If motives of gratitude do not prompt a society to act upon it, the direct return in the enhanced activity of the society, which may be safely prophesied as its effect, ought to decide its adoption. As we said last week, there is every prospect that the July Convention, over which Mr. Humphrey is to preside, will prove a rendezvous of photographic forces calculated to put new life into any society represented at it.—Eds., B. J. P.]

#### COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—In Mr. Otto Pfenninger's letter in the current number of the BRITISH JOURNAL OF PHOTOGRAPHY, Mr. Pfenninger permits himself to make the following statement: "The quasi-instantaneous picture is taken with a Benetto camera, a system which does not give three pictures of equal size—a defect that all cameras with the now known reflector system have." I must demur emphatically to the latter part of this statement. For several years I have worked at a camera of this description, and one of the chief difficulties I have had to overcome has been this difference in the size of the respective tricolour negatives. I claim after prolonged effort to have overcome these difficulties, and the negatives now taken in my single exposure tricolour camera are invariably of identical size, giving in the positives printed from them, by direct contact, perfect register. This statement may be verified by inspection of my exhibits in the BRITISH JOURNAL OF PHOTOGRAPHY's exhibition.—I am, yours faithfully,

EDWIN T. BUTLER.

26, Craven Park, Willesden, N.W.

February 19, 1906.

#### CHEAP ENLARGEMENT OFFERS.

To the Editors.

Gentlemen,—The various methods of fraud adopted by the free portrait swindlers have been freely exposed of late, especially so in your esteemed journal, but I think another system, though differing in method, is nevertheless injurious to the profession. The enclosed (from a weekly magazine) is a sample of what is issued periodically to the public.

The advertisement offers for 5s. an enlargement, for which "the public are informed," a first-class photographer would charge a guinea or more. I venture to say many photographers could be found who, for the price quoted, would do enlargements equal to those of the "Great London Firm." But this offer should be of interest to photographers if only for the statement that "These enlargements are an actual reproduction of the photograph"; also that, "By a new method they are actual enlargements of the photograph itself." Are photographers acquainted with this new method? If not, the competition would require consideration. But putting this aside, unquestionably, coming from such a source, a certain section of the public would accept such misleading statements, and thereby create the erroneous idea that photographers, when quoting fair prices for enlargements, differing from the "new method," were making exorbitant profits.—Yours truly,

MAURICE MEDCALFE.

Oak Villa, Padua Road, Anerley, S.E., February 20, 1906.

[The offer referred to by our correspondent is obviously made in the usual language of plausible advertisement bluff, and, of course, it is no new thing in the methods of attracting notoriety by trespassing upon the preserves of a particular profession. However, these methods seem to be good enough for a so-called religious paper.—Eds., B.J.P.]

ERRATUM.—By an oversight last week the name of Mr. E. J. Wall, F.R.P.S., was omitted from the list of newly-elected judges in the Technical Section of the forthcoming R.P.S. Exhibition.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### TOGRAPHS REGISTERED:—

Brett, 42, Avenue Road, Hampton, Middlesex. Photograph of J. G. Beale, winner of the North of the Thames Chamionship, 1906.  
 Brett, Ewart Lodge, Jameson Road, Bexhill-on-Sea, Sussex. Photograph of the Group of Bechill Harriers with Carey Witherden (Whip.)  
 a & Whittaker, 33, Coronation Street, Blackpool. Two Photographs of a Black Boy in Native Dress.  
 Whiffin, 770, Harrow Road, Kensal Green, W. Photograph of G. Newlands, Queen's Park Rangers Football Club.

**NETTIE COPY.**—I want to copy a small head out of group, and enlarge up to C.D. vignette. The background in group is a brick wall. How am I to proceed to take out brick wall and put in suitable background?—H. C.

Without seeing the picture it is impossible to say what is the best mode of procedure. We should have surmised that any professional photographer, with the picture before him, would see at a glance the best thing to be done. However, here is one way. Copy the figure to the size desired, and then with a retoucher's knife scrape down the lines in the mortar to the same density as the bricks on vignette in the printing. Another way would be to block out the background and then vignette in the printing. Then, by double printing, introduce a hatched background as described on page 2 of our issue for January 5. Of course, there are other ways, but either of these will probably answer your purpose.

**FINISHING.**—I would be glad if in correspondence column in B.J. some indication of "How to use a burnisher" can be given? I have hunted up the subject in the text books, but can find nothing.—B. KILLICK.

You do not say the form of the burnisher you have, but we assume it is of the bar form. First, lubricate the prints by rubbing them over with a solution of Castile soap, twenty grains, and alcohol ten ounces. Heat the bar of the burnisher as hot as the hand can bear, and then pass the prints through two or three times, with sufficient pressure to give the desired polish.

**TONING BATH.**—Could you kindly tell me formula for toning bath or P.O.P.; best darker chocolate tone or black tones for five minutes?—H. V.

The tungstate bath is a very suitable one for warm tones. You will find the formula on page 972 of the "Almanac," where also you will find the necessary baths for black tones, but we would remind you that a formula will not give you a given tone unless the negative is suitable.

**NEGATIVES.**—I shall consider it a favour if you will kindly let me know where I can obtain the following American books in England:—O'Druid's Art of Retouching," "Abbot's Improvement of Negative," "John's Photographic Colour Guide"?—H. G. P.

So far as we know they are not stocked in this country. Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., could obtain them for you.

**NEGATIVE PRACTICE.**—We can only suggest to you that you insert a small advertisement in our columns if you wish to purchase negatives for practice.

**PRINTING.**—Will you please give me the following information?—(1). Would the same result be obtained if a carbon print was printed in winter to the same tint (using P.O.P. as a guide), as was used in summer light? (2). If not, what allowance should be made? (3). Does the increased strength of the bichromate bath affect the gradations in a carbon print? (4). What are the

relative printing speeds of carbon tissue sensitized in bichromate baths of the strength of 1½ per cent., 2 per cent., 2½ per cent., 5 per cent., 10 per cent.?—O. W. I.

(1). No. In a feeble light a proportionately longer exposure is required for carbon. (2). Say about twenty-five per cent.

(3). A weak bath yields more brilliant prints than a strong one. The stronger the bath the softer will be prints. (4). This is difficult to say, as we have never made a strict comparison. But the stronger the bath the more sensitive will be the tissue. We may tell you, however, that a ten per cent. solution is unsuitable, as the bichromate salt will, in all probability, crystallise out on the surface as the tissue dries, that is, if it is left in the bath the usual time.

**BLACKING INSIDE OF CAMERA.**—(1). Would you kindly give me recipe for a flexible paint suitable for camera bellows, either red or black? (2). Also, as blue and violet rays are the most active, would it not be well for studio to be painted in these colours?—E. J. P.

(1). A very good medium for the purpose is Japanner's gold size diluted with twice its bulk of turpentine. With this mix "drop-black" sufficient to cause it to dry dead. (2). There would be no advantage. It was a very old idea to glaze the studio with blue glass and paint the walls blue, but no advantage accrued. Indeed, it was rather the other way about. You will see a note on this subject on another page.

**STUDIO.**—Would you kindly advise me in the following:—(1). Whether plain, or ground glass, for studio, with east light? (2). What best material for blinds for top and side for same?—S. HOWARD.

(1). Either may be used, but we should prefer plain glass, unless there is an unpleasant outlook, in which case ground or fluted glass would be the better. (2). A medium blue, light green, or dark buff blinds, would be suitable for this aspect.

**TINTING.**—I enclose tinted miniature, and should fell obliged if you would kindly let me know the paper on which it is printed, and the method of tinting, etc. My miniatures do not appear to have the same finish as enclosed.—F. R. W.

So far as can be judged, we should say the print is on a thin bromide or P.O.P. paper. The tinting is done with the usual aniline colours sold for the purpose. The high gloss is obtained by squeegeeing the print, while wet, on to a glass plate. The tinting is very neatly done.

**MEMBERSHIP OF THE R.P.S.**—Would you kindly inform me how one can become a member of the Royal Photographic Society, and what is the secretary's name and address?—R. P. S.

A letter of enquiry to the Secretary, Mr. J. McIntosh, 66, Russell Square, London, W.C., will bring you the necessary particulars.

**THREE-COLOUR WORK.**—(1). Why is it that some colour-workers use screens of orange, green, and violet, and others red, green, and blue? (2). Would you please give formulas for the set you consider correct, so that I can make dry ones? (3). What kind of gelatine is the best to use, and will good patent plate glass be a suitable support? (4). Has the abrupt absorption filter any advantage over the overlapping filter —A. M. A. CHAPMAN.

(1). This is a distinction without a difference, due to the careless use of the terms red and blue for orange and violet respectively. Probably, strictly speaking, the screens should be termed reddish-orange, green and blue-violet. (2). The following formulae, which are those given by Dr. König, have been proved satisfactory in practice, and they have the advantage of giving definite formulae for definite areas. The first essential is a 6 per cent. solution of gelatine. Thirty grains of hard gelatine should be soaked in cold water for half-an-hour, the water being renewed twice or three times during that time. It should then be drained and placed in a vessel, and sufficient water added to make the whole weigh 500 grains, then it should be melted by placing in a water bath and finally filtered through mainsack, which has been previously wrung out of hot water. This form the "stock gelatine solution." As very small quantities of dye are required, it is advisable to make up stock solutions of the dyes and then measure out the necessary quantities of these solutions. Blue-violet dye solution:—Crystal violet, 31 grains; distilled water, 1 ounce, 5 drachms; glacial acetic acid, 5 drops. To make the

filter add 118 minims of this solution to  $3\frac{1}{2}$  fl. ozs. of stock gelatine fine solution. On every sixteen square inches of glass pour 118 minims of the dyed gelatine. Two such screens cemented together with Canada balsam form the blue-violet filter. The green dye solution:—Patent blue, 31 grains; tartrazine,  $15\frac{1}{2}$  grains; warm distilled water, 3 ounces, 418 m. To make the green filter add 84 minims of this solution to  $3\frac{1}{2}$  fl. ozs. of stock gelatine solution. On every sixteen square inches pour 118 minims of the dyed gelatine. Two such screens cemented together form the green filter. The red dye solution:—Filter red I,  $38\frac{1}{2}$  grains; warm distilled water,  $3\frac{1}{2}$  ounces. To make the red filter add 68 minims of this solution to  $3\frac{1}{2}$  fl. ozs. of stock gelatine solution. On every sixteen square inches pour 118 minims of the dyed gelatine. Two such screens cemented together form the orange-red filter. The dyes here mentioned can be obtained from Fuerst Bros. (3). Any good hard emulsion gelatine can be used, Nelson, Heinrich, Stoess, Drescher, etc. Thin white patent plate should be used, and the filters should be fitted inside the camera close in front of the plates. (4). This is a disputed point, but the preponderance of opinion is in favour of the overlapping filters.

**OWNERSHIP OF NEGATIVES.**—We have given orders for certain negatives to be taken. These have been made and charged for in an invoice as a separate item, quite apart from the charge for copies or prints. We desire that these negatives be handed over to us, but the operator claims that he has a right to retain them under a "custom of the trade." Please say whether you think he has any such right of retention, having in view the fact that we ordered and paid for the making of the "negatives."—AGARIC.

If you expressly ordered negatives and not prints of the subjects you can demand them. But if you did not do so, the photographer is following the custom of the trade in charging separately for them. An identical case has been so settled in the High Courts. We would refer you to the "Almanac" for 1906, p. 675, where this question is treated at length.

**RETOUCHING** (Reply to H. E. P.).—Your touch is bright and clean, and with more thought and less labour you should make a good retoucher. Vary the touch according to the subject—delicate, fine, and with subtle gradation for wrinkled faces such as that of the lady, and with broader, softer, and easier grain for the men. The character is removed more than even flattery calls for, and you are especially weak and undecided in clearing up in the vicinity of the chin and nose. Your lighting is too edged, and yet not sufficiently marked. Time taken is fair but far from top speed considering the quality of the finish. However, it rests with your own industry and carefulness to attain a much higher standard of workmanship—you have it in you!

**INSURER.**—The fire insurance companies will take risks of this kind.

**ENLARGEMENT CHARGES.**—(1). Is it the correct method to mount the oil-finished enlargements to be had wholesale at 5s. the 12 x 10 size and upwards, behind a gilt or bronze matt, in a glazed frame, or should they be varnished and framed nett size? (2). What is a fair general retail price for the above, without a frame? I am now finishing a standing figure of the King's Royal Rifles, in oils, on 20 x 16 nett bromide. I have been asked to work a more detailed background—the original is quite plain, and have also to work in the medal ribbons. What is a fair average retail price for such a picture, complete, without frame? I have an idea this figure, or any of them for that matter, would look well in the antique oak and enrichment frame, overlaid with English gold, framed direct nett size. An opinion would greatly oblige, especially on the charges above.—MAHLSTICK.

(1). Both methods are followed. We think the close framing is greatly preferable. (2). It is impossible for us to say, as we do not know the time given to the work. Surely you must be in a better position to judge than we are. We think the style of framing would look effective, but here again we do not see how we can advise you on the price.

**PERFLEXED.**—You say nothing about the length of the studio. We advise the longest focus you can use. You may see how long this can be in your studio from the table on page 1,124 of the "Almanac." (2). At least ten or twelve inches, all the better if longer. (3) and (4). It is contrary to our custom to recom-

mend individual goods. (5). It is impossible to compare all the lenses of one maker with all those of another, and in any case we should not draw comparisons between individual lenses. In many instances they are different in character, and are to be preferred for different reasons.

**N.D.P. NOVICE.**—No print was enclosed. There is usually no difficulty in attaching P.O.P. prints to glass. They should not be hardened in alum or formalin, and it is all the better not to let them dry before fixing them on the glasses. With these two precautions, you should have no trouble in getting them to hold after squeegeeing down.

**COPYRIGHT.**—Some little time ago I procured a very good photograph of a village church, and issued picture postcards from the negative. A copy has been handed over to the printers, from which they have made a block and printed same on cover-page. I have not copyrighted the picture. (1). Have I any redress? (2). Who is responsible for the copying—the printer, or the person handing the copy to him? (3). Is it possible for me to copyright, and then take proceedings against the parties conjointly?—SURFON.

(1). No. (2). The printers in this case. (3). Not for infringement before registration.

**R. D. M.**—Certainly, an anastigmat is what you require. You had better consult the makers' lists (in the "Almanac") for one. For flashlight purposes it will be sufficient to select a rapidity of f/7 to f/8.

**G. H. T.**—We should not use pyro-soda for rapid development. If speed is important you would do better with pyrocatechin or kachin, both of which are good developers in other respects. You should use the formulae, with caustic soda as the alkali.

**A BOOK QUERY.**—Will you kindly recommend good books for a beginner who wishes to study chemistry and optics as connected with photography? Also books dealing with colour-photography?—BEGINNER.

"Light, Visible and Invisible," by Professor Sylvanus Thompson; "Optics for Photographers," by W. K. Burton; "The Chemistry of Photography," by C. F. Townsend; "Colour-Photography," by Bolas, Tallent, and Senior.

**COATS OF ARMS, ETC.**—Would you kindly let me know if I must obtain permission from anyone to place the borough or town coat of arms upon pictorial postcards of the said district (photographs not impressed)? (2). Where I can obtain the ivory-coloured embellishments to place over the corner joints and around the openings of frames, as illustration herewith? (3). Where I can obtain a cheap plaster bust to practise photographic lighting? (4). Please advise me as to a tasteful colour and style for interior decoration of show cases to harmonise with different colouring of mounts and photographs?—TASTEFUL.

(1). We believe no permission is necessary. Why not write the town clerk of the borough for information? (2). We cannot say. Possibly from the firms mentioned under (3). (3). From firms in the Italian quarter of London, such as G. Baldacci, 31, Hatton Wall, E.C.; D. Lardi, 36, Charles Street, Hatton Garden, E.C. (4). A neutral dark grey packing paper is as good as anything, and is very cheap; or, if the case is of fair size, a fine atlas cloth of neutral shade, such as you can get from Burnet's, of Garrick Street, W.C., is very suitable. We advise you to avoid strong colouring in the decoration.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

**Colour-Photography.**—Complying with numerous requests the Exhibition of Colour-Photography at these offices will remain open until March 17. Since the opening twenty-one additional exhibits have been hung. (P. 163.)

**Artistic Lenses.**—An exhibition of the work of the Puyo-Pulligny series opened in Paris yesterday. A full review by M. Demachy, articles by MM. Puyo and Pulligny, and an art supplement, illustrative of the results of the lenses, will be features of next week's issue of the B.J.

**Enclosed arc lamps** are now coming extensively into use for printing print-out papers, for enlarging and for portraiture. C. H. Hewitt, the Regent Street Polytechnic, deals with their properties and manipulation. (P. 164.)

**New developers and a three-colour camera** are among the patents of the week. (P. 174.)

**A diazo process of photographic printing on silk** has been worked out by Frank J. Farrell, M.Sc. Printing is done from a positive, and a considerable range of tones is obtainable. (P. 167.)

**A review of theories of the latent image**, communicated to the London Provincial Photographic Association, A. J. Bull concludes that the present evidence supports a physical theory. (P. 169.)

**Standards for photographic materials and apparatus** are specified in the belated report of the International Congress of Photography, which last July adopted resolutions as to colour sensitiveness, latitude, &c. (P. 171.)

**The Birmingham Exhibition** appears to have made quite a small sensation by its presentation of a phenomenally fine collection of pictorial work, including that of workers hitherto unknown in this country. Exhibition closes on Monday next. (P. 172.)

**A vendor of objectionable postcards** has been sentenced to three months' hard labour without the option of a fine. (P. 180.)

## EX CATHEDRA.

### Hard Labour for Postcard Vendors.

It is to be hoped that the sentence of three months' hard labour passed upon a dealer in improper postcards at Hastings last week will be a salutary warning to all stationers and other shopkeepers who may be tempted to transgress the conventions of decency in the sale of postcards of a questionable character. We shall be glad to see the full power of the law put forth to punish offenders of this class, and probably a few more sentences of this kind will show the wholesalers in these cards that magistrates up and down the country are determined to deal severely with offenders. In one case brought up at Marlborough Street, the invoices from the vendors of the cards were produced in Court and placed in the hands of the police, a practice which other magistrates might follow with advantage, for spasmodic seizures of retailers' stock cannot be expected to be effective in bringing the makers of the offensive cards to book.

\* \* \*

### Useful Bargains in Old Lenses.

While an old type of rapid rectilinear designed for use in a quarter-plate camera is not likely to be much of a bargain, however cheaply it may be obtained, the case is very different with lenses of greater focal length. An eight-inch R.R. lens that, judged by modern standards, is useless for half-plate work, may cover a quarter-plate excellently at its full aperture. Such a lens can frequently be met with, and while it may cost a pound or so if it has the name of a well-known maker on the mount, it can be picked up for only a few shillings if nameless. Not long ago we secured such a lens for five shillings, and it has proved to be a really valuable acquisition for quarter-plate work at  $f/8$ , though it is useless on a half-plate with any greater aperture than  $f/16$ . Many of the old nameless lenses were of French manufacture, and while they will fetch practically no price at all in a modern saleroom, some of them are really useful. They are somewhat bulky compared with modern lenses, but an old "half-plate" R.R. can generally be fitted to a quarter-plate camera without any trouble. Occasionally a Darlot lens is to be met with, and one of that make is likely to be very serviceable. The name is, however, not always on the mount, and when it is it may not be readily recognised. It generally takes the form of A.D. crossed, one letter being vertical and the other horizontal, and this hieroglyphic is sometimes only to be found marked in pencil on the ground edges of the glass lenses.

\* \* \*

### Artistic Lenses.

Yesterday there was opened at the Photo-Club of Paris an exhibition of the results of the anachromatic lenses to which Major Puyo and his colleague M. Leclerc de Pulligny have drawn attention of

late, and the optical calculations for which, we believe, are due to their associated work. The selecting committee includes M. Bucquet, the President of the Photo-Club, M. Demachy, M. Puyo, and M. Pulligny; and the exhibition is open free of charge daily from 10 to 6, at 44, Rue des Mathurins. The lenses, it may be remembered, were the subject of an article in our columns a little over a year ago, and since that time have been taken up to a considerable extent by photographers with aims in the direction of pictorial portraiture. We shall deal fully with the exhibition next week, when a review from M. Demachy will appear accompanied by articles on the lenses by Major Puyo and M. de Pulligny. With the same issue also will be presented a supplement in the shape of a piece of portraiture made with the lenses.

\* \* \*

### The Birmingham Exhibition.

"Your show is a revelation," wrote Mr. W. R. Bland, one of the judges, to a member of the Birmingham Society. Mr. Alex. Keighley, another judge, stated that he had never before judged at a show of such excellence. A review of some of the good things now to be seen in the rooms of the Royal Society of Artists, New Street, appears on another page. The Birmingham people have towers of strength in their midst, but this year's show is not in any sense local. Nor even national: for the foreign exhibitors take a large and prominent place. Among them are well-known workers such as Demachy, Puyo, Dürkoop, but also a dozen others who are new to Great Britain, but must be reckoned in future among the pictorial leaders. Birmingham, during the time the exhibition remains open, should be, as it deserves to be, a rendezvous of those who would embrace a unique opportunity of judging present-day pictorial photography. The Exhibition closes on Monday next.

### Colour Photography in Advertisement.

If anybody wants a parlour demonstration of three-colour printing he can get one for nothing from the proprietors of a universal infant food. The latest advertisement novelty to reach our table takes the form of a single piece of "crystal" paper on which are printed three impressions—red, yellow, and blue—of the same subject. The printed instructions enable the lay person to fold the paper so as to superimpose the pictures, when a multi-colour effect of a kind is seen on holding the folded sheet up to a light. In the particular specimen which has come into our hands the result is far from satisfactory; and probably the inks used for the three components would make Mr. Carl Hentschel's hair stand on end. But the idea might be utilised for the advertisement of the three-colour process.

\* \* \*

### Smoothness of Working.

The less the machinery of photographing is in evidence in the studio the better the portrait, may be regarded as axiomatic. The adjustments of blinds or curtains, the movement of backgrounds, and the manipulation of the camera should all be made as simply and quietly as may be. One of the great advantages of spring roller blinds is that little more than a touch, particularly if a patent clutch to hold the cord is used, is necessary to let in more light. Curtains on strained wires are usually manipulated by means of a long rod, and more time is occupied and the work is more fussy. Blind cords should be renewed from time to time, to prevent the possibility of a breakage during a sitting. All the casters on background stands, tables, and the camera stand should be slightly oiled from time to time, so that

the movement is as easy and as silent as possible. The head rest is rather difficult to keep in smooth working order. If the sliding parts are thoroughly cleaned and made bright and then coated with vaseline, which may be almost wiped off again, rusting will be prevented and the sliding movement kept free and easy. The camera stand deserves more attention than it generally receives. The rack and worm screw for raising and lowering the camera should be kept clean and nicely oiled. There is a tendency for it to gather dust and become clogged and stiff. Wooden parts working against each other may be lubricated with black-lead or French chalk. The smooth working of dark slides is a matter only obtained by the use of well-made slides, constructed from well-seasoned wood. Early dark slides were polished inside as well as out, and the wood much better protected from climatic changes. Both slides and camera should be kept dry, if easy working and uniform light-tightness is desired.

### COMBINATION PRINTING.

At one time—now some thirty or forty years ago—the qualifications required in a photographic printer were considerably greater than they are at the present time. Then a printer was expected to be able to print in fresh and shaded backgrounds, or maybe to change them; or at times to combine two or more pictures into one. As an example of what used to be done it may be mentioned that the majority of the late Mr. H. P. Robinson's pictures were printed from several negatives. Also, that the once famous picture, "The Two Ways of Life," by Rejlander, which attracted a great deal of attention at the time it was produced, was printed from something like three dozen different negatives, yet the junctures could not be detected so dextrous was the work done. Many modern printers, if called upon to change a background or introduce one or more figures into a group, would not know how to set about the work, as witness the queries that are constantly being considered in the "Answers" column. Only last week we replied to a correspondent, a professional photographer, who did not know how to produce a vignette portrait out of a group of several people.

In combination printing two systems may be followed—either masking, or vignetting the one picture into the other. The latter is, perhaps, the better, but requires greater skill and more experience to get perfect results than does the former; hence this method will here be considered. We shall not attempt to enumerate all the "dodges" that may be resorted to, even in masking, but will describe a couple of simple methods that will, with a little ingenuity on the part of the worker, enable him to do anything in this direction that he is ever likely to be called upon to undertake.

By way of example let us assume that an extra portrait is required to be introduced into a group already taken, or maybe, to replace one of the figures, that may have moved when the picture was taken, by a more perfect one. Let us say the picture is 12 by 10, and contains several figures. If the portrait to be introduced has to be taken specially, it should, of course, in size, lighting, and density be made to correspond with those in the group. If it has to be made from another photograph this should be reproduced the proper size, and a half-plate would be suitable for the purpose. The negative having been obtained, a print is made from it on, preferably, thin paper. Next the figure, or so much of it as may be required to appear in the picture, is cut out neatly with a sharp-pointed penknife, and the two portions exposed to light until the paper is blackened.

the figure-portion is then adjusted in position on the large negative, and firmly secured with a few touches of diarrubber solution. This cement is preferable to others, inasmuch as it does not cause expansion of the paper, and the mark can be easily removed, without injury to the larger negative. The other portion—the background mask—is similarly cured on the small negative. This being done the group negative is printed in the ordinary way, and the print will, of course, have a white space left to receive the new figure. The group negative is then removed, the single figure one put in the proper position—the margins being extended by black or yellow paper to protect the already printed portions—and the second printing done, care being taken that the depth in the second printing is the same as in the first, otherwise there will be a difference in tone in the finished result. If the work be neatly done the junction of the two printings will not be seen. If it is, it must be touched in with colour, and this should not be required. Here we have assumed that only one figure has to be introduced, but it will be obvious to all that several may be put in in the same way. There is another very simple method of accomplishing the same end which some may prefer to the one just described. In this the single-figure negative has the background, and such portions as are not required, blocked out with black varnish, or a blackened cut-out mask as in the dye method. The figure is then printed on a piece of albumen, or collodio-chloride paper, a little larger than the large negative, and approximately in the position it is to occupy in the group. All the paper beyond the small

negative must, obviously, be protected from light during the printing. We then have the figure, alone, on white paper the full size which the finished picture is to be. The printed figure is now neatly painted over with gamboge and allowed to dry. This print is then put into the right position on the group negative, which is then printed as usual; the gamboge protects the already printed image from further action of light. After the printing is finished the print is washed, toned, and fixed in the ordinary way. In the washing out of the free silver from the paper the gamboge dissolves away and leaves the image clean. The reason why albumen or collodio-chloride paper is advised in this method is that, with some makes of gelatine paper, the gamboge would be liable to leave a yellow tint behind, but with either of the others no such trouble will arise.

In combination printing, whatever method be employed, care should be taken, more especially when several printings have to be done, that the paper is in the same hygroscopic condition in the different printings, for it goes without saying that if it expands or contracts between them accurate registration will not be obtained.

In double or combination printing great neatness and some care is necessary with every print, and if many are required the work becomes a little tedious. Therefore, if, say, several dozens of the same subject are required, it is better to make a combined negative. Such a combination negative is by no means a difficult thing to make, but it requires neatness and some skill in the work, and if only a few prints are required it is scarcely worth the trouble involved.

## COLOUR PHOTOGRAPHY.

The Exhibition of Colour Photography, opened at these offices on January 19 last, was announced in our last issue to close at the time appointed, viz., to-morrow, March 3. During the few days, however, we have received quite a number of letters asking for an extension of the time during which there may be an opportunity of viewing the collection, and we have therefore provided for the exhibition to remain open another fortnight, i.e., until Saturday, March 17. It will then be finally closed, and the specimens returned to the ladies and gentlemen by whose courtesy and kindness we have been enabled to bring together a collection which, we are assured on all hands, has been an incentive and impetus to colour photography. Since the opening of the exhibition the responses to our offer to add exhibits to those already catalogued have resulted in additions to the number of twenty-one, and the present occasion may be seized as a convenient one to describe

these examples with a view of supplementing the catalogue. The following are the added exhibits:—

Portrait from life on Rotary three-colour stripping pigment films—The Rotary Photographic Co., Ltd.

Snap-shots in colour (three-colour prints)—Captain. Lascelles Davidson.

Copy of a painting on Rotary carbon tissue—E. R. Grills.

Solgram colour print. Turner's "Temeraire" three-colour Sinop print—S. G. Yerbury.

Three-colour prints by ferro-prussiate and gum processes—Rev. Johnson Barker.

Portrait of the King. Three-colour reproduction of a

painting by the Sanger-Shepherd process—E. R. Grills.

Three-colour transparency, on two glass plates with film interposed. Enlarged to whole plate from quarter-plate negatives—The Lady Saltoun.

Transparency by the MacDonough-Joly process—A. V. Kenah.

Two transparencies by the Jumeaux process—Otto Pfenniger.

Six three-colour Pinatype prints—Henry J. Comley.

Three-colour print on "Rotary" stripping film—Henry J. Comley.

any example which other photographic societies might well find their advantage to follow was recently set by the Dundee and of Scotland Photographic Association. Recognising the claims of the ladies included in its membership roll it set apart an evening especially for their instruction. A large attendance of both sexes was the result. The subject for the evening was "Carbon printing," and the lecturer was Mrs. Vanessa C. Baird.

The Liverpool Amateur Photographic Association, in issuing its annual report, has to chronicle a practically stationary membership, yet is able to record a balance to its credit, and a year of successful work. The library is said to have been overhauled, and its present condition is represented by the catalogue appended

to the report, we suggest that one of the first duties of the Society is to place a few later editions of standard works on its shelves. Apparently, it has not purchased a single volume on photography during the past five years. It might well invest, say, a later edition of Wall's "Dictionary" than 1895, of Chapman Jones's "Science and Practice" than that of the same year, and it does not appear to possess Abney's "Instruction in Photography" at all.

MR. WALTER D. WILFORD is announced in the February and remodelled issue of the "Motorist and Traveller" as its art editor. Our motoring contemporary is now in the hands of Mr. A. J. Wilson, and is a large and handsome production which is extremely good value at threepence.

## ENCLOSED ARC LAMPS IN PHOTOGRAPHY.

COMPETITION is so keen nowadays that the somewhat leisurely methods of the past will no longer suffice if the worker is to hold his own. One of the features of the last three or four years has been the increasing reliance of the portrait photographer on bromide and gas-light papers for dull weather, and for orders required in very short time. Excellent as are the results, and simple the working of these papers, there are cases where something different is required, and the question often asked is, "How can I get prints by other processes than these, when daylight is not available?" The partial printing and subsequent development of P.O.P. which from time to time has attracted the attention of professionals, is but an indication of this want. What applies to printing applies equally to other photographic work, such as enlarging and exposures in the camera for portraits, copying, or the photography of objects such as silverware, vases, and small articles of furniture. An illuminant, then, which may be readily installed, and be available for any or all of these everyday purposes, should prove exceedingly useful in any studio which is as busy as its owner would like it to be, and I venture to think such a lamp, if its powers are made the most of, will at once increase the capacity and speedily increase the output.

It must not be supposed that a powerful light, such as an enclosed arc lamp, can be bought and put into safe and efficient use quite so easily as a fourpenny incandescent gas mantle. There are certain points which require careful attention not only in the use, but in the installation of the lamp. It will perhaps be better to briefly indicate the uses to which a lamp of the enclosed type may be put, and to point out those methods of use which are calculated to give the best results. One or two convenient ways of making the installation may then be suggested, so that the maximum of efficiency may be obtained with the minimum of expense and trouble in working. It may also be well to state at once that reference is made to the enclosed arc lamps of the Westminster Engineering Company. They are, so far as I am aware, the only enclosed arc lamps at present on the market specially designed for photographic work. As will be seen from the Westminster Company's list, their photographic efficiency is guaranteed by the published tests made here at the Polytechnic Institute, and the details and information given in this article have been obtained from work done at the Polytechnic, where the proper adjustments for the most efficient actinic intensity were first studied and applied to pure photography and process work.

PORTRAIT BY ENCLOSED ARC LAMP. By C. H. Hewitt.

The lamp was placed 8 to 10 feet from the sitter, and an exposure of 2 to 3 seconds given at  $f/6$  on a plate, 300 H. and D.

### Printing.

For printing by any of the daylight processes, the lamp is best suspended near the floor so that the printing frames may be set round in a ring. By having a circular gallery a double ring of frames may be printed, one ring above the other. A good average distance from the lamp is two to three feet. The number of frames which may be printed at once is not an important point, as the time of printing is so short. For instance, with a negative of reasonable thickness, a platinotype print may be made in two or three minutes under ordinary working conditions, and in less time if it is held nearer to the lamp and kept moving to equalise the light over the negative. P.O.P. or colloidal chloride will require a little longer, and carbon longer still, especially if the negative be rather thicker, as well as denser. When the lamp is burning steadily, the crater of the positive pole being in the centre of the end of the carbon, the light is practically uniform all round the lamp. Occasionally, through imperfections in the carbons or inaccuracy of alignment of the two carbons, or, through the enclosing of the arc not being quite perfect, currents of air affecting the arc, the light is brighter on one side. But under normal average conditions the light is uniform all round the lamp, and if the negatives are even in thickness and printing quality, it is quite possible to print by time. For instance, we have recently printed at the Polytechnic a batch of platinotypes in this way, classifying the negatives, ascertaining the time required, and then exposing fifteen or eighteen frames set round a chalked circle for that time. A greater degree of uniformity is obtained than by making a visual examination of the prints, and the work is more rapidly got through.

The lamp may be suspended over a work-bench to avoid stooping to the floor, but the light being then on a level with the eyes, some shield is needed. Such a shield is better used in any case, as the light is very concentrated and powerful. Care must be taken not to allow the bottom of the lamp or the lower carbon to touch the bench or floor, and particularly any metal, or short circuiting will probably occur. The lamp should be suspended so as to swing clear of everything. To prevent scorching of the woodwork or floor, a sheet of asbestos is an advantage. The heat given by these enclosed lamps is considerable, and in carbon printing it is very necessary to keep the frames at a sufficient distance so as to avoid heating the carbon tissue. Tissue, overheated, becomes practically insoluble, and even if only partial insolubility exists, the degrading of the high-lights is fatal. With

printing process it is well to have the negatives a little stronger contrast, as the powerful light penetrates the opacities of the negative more than ordinary daylight. I have noticed the greatest difference between daylight and arc light prints from the same negative in the case of the carbon process. Where the tissue is sensitized by the worker himself it is possible to get excellent prints from ordinary negatives by using a weaker sensitizing bath, going even as low as a one per cent. bath, so that no trouble need be apprehended.

enlarge from negatives covered on the back with matt varnish without any great amount of granularity showing in the finished result. A sufficiency of light makes it possible to do a good deal of shading; or dodging during the exposure on the bromide paper. The exposure may be increased, if desired, by using a smaller stop in the lens, until it is, say, a minute. This is neither too short for easy manipulation of the shielding card, nor so long as to make the manipulation tedious. Negatives made for contact printing in C.C. or platinotype

Miss Vera Morris.

Miss Ethel Reason.

Miss Sylvia Smythe.

PORTRAITS BY ENCLOSED ARC. By Miss Annie Bell.

The lamp was used 6 to 8 feet from the sitters, one thickness of clean blue tracing cloth used as a diffusing screen, and the direct light allowed to fall on floor and the reflector. Exposures, one-third second at  $f/5.6$  on a 250 H. and D. plate.

Another point I have observed, but have never seen mentioned elsewhere, is that when using such a concentrated light the Newton's rings formed by pressure of the negative against the sheet of glass in the printing frame, will print on to the printing paper. This occurs sometimes when making contact dry-plate transparencies in the dark-room, using incandescent gas or electric lamps, if the negative is not kept moving, and the same remedy may be applied when using ordinary daylight processes by the enclosed lamps.

**Enlarging.**

When making use of the lamp for enlarging, whether direct on to bromide paper or from transparencies for enlarged negatives, great care must be exercised to keep the lantern from getting overheated. With a light of this intensity the danger of fogging the sensitive material by stray light is much greater than when an oil lamp or incandescent gas is employed, and it becomes necessary to carefully use in the arc lamp. Then arises the danger to which I have alluded, that of overheating. It is possible by continuous burning to get such a degree of heat as would seriously endanger the insulation of the wiring in the lamp. This risk is obviated by switching off the current after each exposure, but it is preferable not to switch between a trial and the actual exposure, as the light might vary some extent. A double switch, closed in, should be used. With the double switch, the spark or flash occurring when switching is more than sufficient to fog any bromide paper which may be covered in the room.

The strength of the light enables much to be done in an electric arc lantern which is either impossible or inconvenient with less powerful illuminants. One or two thicknesses of ground glass may be used between the light and the condenser, equalising the illumination of the negative without seriously prolonging the exposure, and giving a light more like daylight, in that minute defects in the glass, or film, or specks of dust in the varnish are not glaringly apparent on the enlargement. With a light diffused in this way it is possible to

are too strong for enlarging with the ordinary gas or oil lantern. With an arc lamp they give excellent results, and slight differences in strength may readily be compensated by selecting a bromide paper of suitable character. When very strong negatives, such as those for carbon, have to be enlarged, the use of the "grader" will probably be necessary, but if a fairly open lens aperture is used the exposures even then need never be prolonged. Assuming the average increase of exposure due to the grader as fifteen times, and a negative strong in contrast, but not unnecessarily thick, an exposure of 1 to 1½ minutes would be about the usual time, with ordinary bromide paper, and enlarging from half-plate to 15 x 12, i.e., two to three diameters.

When thin negatives have to be dealt with a piece of pale yellow glass may be placed at the back of the negative, and will not only increase exposure until it is of manageable duration, but will also tend to increase the contrast in the enlargement. Such a glass may be obtained by dyeing (with a very weak solution of tartrazin) a fixed-out and washed lantern half-plate.

**Portraiture.**

The requirements in a light for portraiture appear to me to be the following:—

1. Safety, that is freedom from risk of fire from short circuiting or from falling broken carbons.
2. Cleanliness, so as to protect the studio and sitters from dust and dirt.
3. Comfort, freedom from heat or excessive glare, or hissing or roaring of the light.
4. Efficiency, ensuring sufficient light to enable a good distribution to be made.
5. Simplicity, the lamp not needing too frequent an adjustment or being difficult to adjust, or so complicated as to get out of order frequently.
6. Economy in maintenance and in consumption of current.

Let us apply these to the enclosed type of arc lamp and see how far it will answer the requirements. As regards safety, much depends on good and careful construction, and the lamps being well made it only remains to have the wiring carefully done by a competent electrician. One of the dangers of the open arc is that carbons may break, and falling to the floor may set dresses or furniture on fire. With an enclosed lamp this can hardly occur. Care must, however, be taken to fasten the lower carbon very securely with the clamping screw, or the metal plate forming the bottom of the lamp will expand as the lamp gets hot, and the carbon not expanding to the same extent will be likely to drop out.

In point of cleanliness the enclosed arc runs an incandescent electric lamp very close. Not only are the products of combustion reduced to the minimum by the fact of the arc being enclosed in an almost air-tight glass cylinder, but this cylinder keeps any dirt and fumes from escaping and settling in the studio.

No artificial light can be regarded as satisfactory unless a fair degree of comfort is ensured for the sitter. For freedom from glare with great actinic power, steadiness of light, and absence of great heat, the enclosed type of arc lamp is satisfactory.

The power of the light is amply sufficient, as may be seen from the illustrations and the particulars attached thereto. The portraits of children show what can be done in the way of cutting down exposure, while the half-length portrait in which the light has been controlled so as to secure some concentration of light and shade was given an exposure of from two to three seconds under the conditions stated.

A lamp for portraiture which requires any attention is more or less a worry as compared with daylight working, where the light may be said to require no attention at all. If the artificial light requires constant or frequent attention, that is, if adjustments need to be made every few minutes, and perhaps more frequently than this, the mental strain of operating, always great enough on account of the many variable factors, the attention to small details and the securing of proper expression, is materially increased. When the light approximates to daylight in steadiness and continuity, more attention can be given to these details.

### Installing the Lamps.

Inquirers who contemplate installing artificial light usually ask first as to the cost per exposure. In any case the cost of running cannot be high relatively to the price obtained for the finished photographs. It is hardly possible to give more than approximate figures, and, of course, with a continuous burning lamp the cost per exposure depends on the time taken by the operator in posing and exposing. It seems better, therefore, to give the cost of running per hour. The Westminster No. 114 lamp takes 6 to 7 units per hour, and the smaller No. 111 lamp takes  $3\frac{1}{2}$  to 4 units. On a day load at 2d. per unit the cost is thus seen to be from 1s. to 1s. 2d. per hour or 7d. to 8d. per hour respectively. To this must be added the cost of the glass cylinders and the carbons. With care the cylinders should last a long time. If two new carbons are fitted to the lamp it should run easily for three hours without renewal, though in that time the lower carbon may need raising once or perhaps twice. The enclosing of the arc effects a vast economy in carbons. Using the smaller or No. 111 lamp, therefore, the cost may be estimated at 8d. for current and, say, 4d. for carbons and glass cylinders, which is an ample allowance. Taking five minutes as sufficient time for an ordinary sitting with two or three exposures, the cost works out at a penny per sitter. In the case of the installation for the photography at the Mansion House, to which further reference is made below, the lamp was burning for nearly seven hours, and seventy-five units were used, at  $3\frac{1}{2}$ d. per unit. The number of plates exposed was 450, the cost thus working out at about a half-penny per plate. In this case the rate per unit was higher than is usually charged, and photographers have now little or no difficulty in getting current at the power rate for arc lamps.

We must now turn to a brief consideration of the methods of installation. If one lamp is to be used for printing and enlarging, as well as portraiture, the smaller size will be the more convenient. It may be suspended in an umbrella-shaped reflector, the light being covered in by means of a wire framework shaped like an inverted beehive, and covered with tracing linen cut in gores and lightly sewn on. Fig. 1 roughly indicates the arrangement shown in section. The

wire umbrella, six or seven feet across, is covered with taggers or with thin sheet zinc from the top to A B, the remaining portion being calico tightly stretched, and the whole coated inside with white paint or distemper. The wire beehive is attached at A by two hooks to rings on the umbrella, and at B by one hook, so that it may be unhooked here and allowed to swing down to allow of access

Fig. 1.

Fig. 2.

the lamp for replacing or adjusting carbons. At D a three-fold screen, eight feet high and covered with white blotting paper, is placed, giving ample side light and obviating too great a concentration of light. On the shadow side of the sitter another large reflecting screen of white blotting paper is placed to illuminate the shadows. By its size and by being placed at the right distance from the sitter false reflexes in the eyes are, to a great extent, avoided. The arrangement of the lamp is practically that employed at our Polytechnic Studio Operating Classes, where Mr. Howard Farmer has always advocated softening contrast by the raising of the tone of the shadows, thereby materially diminishing the exposure, in preference to the lowering of the tone of the high-lights by means of additional diffusing screens.

Instead of the beehive shaped diffuser the lamp may be left entirely open and an ordinary tracing linen head screen employed to prevent the direct undiffused light reaching the sitter. The lamp was so arranged for Miss Bell's work at the Mansion House Ball, an account of which was printed in the issue of THE BRITISH JOURNAL OF PHOTOGRAPHY for January 12, 1906. The photographs of children accompanying this article were produced on that occasion, and are reproduced by Miss Bell's kind permission. The head screen was so placed as to allow the direct light from the lamp to reach the floor, and the whole of the shadow side reflector, the large amount of reflected light from the interior of the umbrella, and from the three-fold screen, preventing any indication of the direct character of the light on the lower part of the subject.

C is a counterpoise weight which allows of the lamp being raised for full-length standing figures. The lamp may, of course, be hung at a fixed height and from a travelling pulley, but this is, in the majority of studios, quite unnecessary.

An alternative arrangement which we have used experimentally, and which has worked exceedingly well, is to suspend one of the smaller size lamps about three feet from the wall, which is covered with white blotting paper or a white lantern sheet, simply using a large tracing linen head screen for diffusing, as shown in Fig. 2. Working in this way the lamp may be very conveniently lowered for printing, or the cable may be detached, the lamp lifted down, and taken to the enlarging lantern or the printing room.

In portrait work it is most important to use a very efficient lens shield, or the plates will be badly fogged by light striking the lens.

is, of course, should be done with daylight work, but it is much more essential where the light is in front of the lens rather than at the side, and with artificial light the close proximity of the source of light to the sitter often brings the lamp only just outside the field of view. Possibly the best form of lens shields is a kind of box, the front of which may be moved nearer to the lens, or further away, as required. The opening in the front, reversible like the shutter of a camera, for upright or oblong portraits, should be arranged to allow nothing to be seen on the focussing screen except the required picture.

If the lamp is used for copying, care must be taken to secure even

illumination. With small prints no difficulty will occur, but when a large picture, says 15 to 20 inches in length, is to be copied, it will be necessary to use a reflector. Of course, the best arrangement is that adopted in process work, where two lamps are employed, one on each side of the original.

For enlarging, the most convenient method of using the same lamp in the lantern would be to have a large Russian iron box made, taking care to secure light tightness, with ample ventilation. The condenser should not be of too short a focus, so that it may be kept well away from the lamp and any risk of breakage removed.

C. H. HEWITT.

## A METHOD FOR THE PRODUCTION OF PHOTOGRAPHS ON SILK.

(A Paper read before the Society of Dyers and Colourists).

In 1896 a series of experiments was made by Mr. Ernest Bentz and myself on the diazotisation of the wool fibre, the results of which are published in a short paper read before the Manchester Section of the Society of Chemical Industry, and printed in the Journal of that society.

The object of these experiments was to determine whether the dyeing properties of the wool fibre depended in any degree on the assumed presence of an amido or imido group in the molecular complex of the fibre.

In order to accomplish this it was necessary to make dyeing experiments with wool in its unchanged condition, and wool from which the amido or imido group had been removed. The removal of the amido or imido group was effected by the well-known method of azotising (whereby the wool was rendered deep yellow in colour) and boiling. It became necessary to prove in the course of these experiments that the immersion of the wool fibre in a solution of nitrous acid was actually converted into a diazo (or diazonium compound). This was readily proved by experiments showing that combinations with alkaline, aromatic hydroxy compounds could be effected, coloured bodies being produced, the colour varying with the hydroxy compound employed from yellow to red or brown. For example, combined with beta naphthol a bright red shade is produced; with resorcinol a golden orange.

During the conduct of these experiments it was found that the light yellow colour of the diazotised wool fibre rapidly changes under the influence of sunlight, becoming very pale buff or deep cream in shade. When this change has occurred it is no longer capable of combining with alkaline hydroxy compounds.

The sensibility of the diazo compound to light suggested the possibility of applying the process photographically, and experiments showed that prints could be obtained. Owing, however, to the loose and fibrous surface of all wool fabrics, the prints produced were more or less blurred and indistinct, most of the fine detail being lost. The process was therefore only applicable in certain classes of subjects where the result depended more upon the broad general effect than on the sharpness of the finer details.

This defect led to a series of experiments with the silk fibre, which is also assumed to contain an amido or imido group in its molecular complex. It was found that the silk fibre by immersion in cold dilute solutions of nitrous acid for several hours was rendered deep yellow in colour, as in the case of wool, and that the colour so produced could be converted into coloured bodies by combination with aromatic hydroxy compounds in alkaline solutions. The yellow body, which I will call the silk diazo compound, is like the wool diazo compound, very sensitive to light. As silk fabrics can be obtained with a beautiful even surface—for example, satin—it seemed probable that a successful photographic process could be based on the sensitiveness to light of the silk diazo compound.

### Diazotising Silk.

In converting silk into the diazo compound, the fabric is first carefully washed to remove finishing matters, and any grease or soap left in the silk after the boiling off process. After rinsing well in water, it is immersed in a solution of nitrous acid made by dissolving 1 per cent. sodium nitrite in cold water and adding 1 per cent. of sulphuric or hydrochloric acid. The operation should take place

in the dark or in a room dimly lighted by artificial light. The silk remains in the nitrous acid for about six hours, and should be moved about from time to time to prevent the accumulation of gases under the folds of the fabric, which might lift it above the surface of the liquid and lead to the production of uneven results. The silk is now well rinsed in water, and after wringing or hydro-extracting, is dried at a moderate temperature under tension in the dark. The object of drying under tension is to produce an even surface ready for the printing process. The diazotised silk thus dried will keep in the dark unchanged for several months.

### The Printing Process.

The portions of the fabric which are exposed to light during the printing process are changed from the diazo compound into a body which is incapable of forming coloured compounds with alkaline solutions of hydroxy compounds, the portions not affected by light remaining unchanged and still capable of combining with hydroxy compounds. Hence it is obvious that printing must take place beneath a photographic positive and not beneath a negative, as in photographic processes depending upon silver compounds.

After exposing under the photographic positive the silk is ready for the process of development. This is effected in dilute solutions of aromatic hydroxy compounds in caustic soda or caustic potash, the colour produced depending upon the hydroxy compound employed.

It is found that the best results are obtained when the developing solution is warm, the temperature generally employed being from 25 degrees to 30 degrees C. Half per cent. solutions of the hydroxy compounds are used in a half per cent. solution of caustic soda or caustic potash. The caustic alkali solution of this strength has little or no action on the silk fibre at 30 degrees C. during the short time the development is carried out—a few minutes.

### Red, Brown and Violet Tones.

Development with beta naphthol produces a crimson shade, which, after well washing and finally rinsing in a dilute solution of acetic acid, becomes scarlet.

Alpha naphthol produces a duller and bluer shade than beta naphthol. Development with alkaline resorcinol produces a bright red, which, after washing and finally rinsing in dilute acetic acid, becomes golden orange. Other hydroxy compounds may be employed, the shades produced varying from yellow to red and brown. The colours produced in this manner may be considerably modified or altered by immersion in cold or slightly warm dilute solutions of certain metallic salts, e.g., iron, nickel, copper, chromium, cobalt, etc.

The golden orange produced by development with resorcinol is converted by dilute solutions of ferrous sulphate into a very dark brown by nickel salts into maroon, cobalt salts into red violet, etc. The red obtained from beta naphthol is converted by iron salts into a red brown, and into blue shades of red by nickel and cobalt salts.

Similar results are obtained by treatment with solutions of metallic salts of colours obtained with other developers.

Experiments were next made to determine whether the silk diazo compound would combine with aromatic amido compounds. In cold or slightly warm solutions negative results were obtained, but it was found that at or near the boiling point combination would take place.

With dilute solutions of alpha naphthylamine, at or near the boiling point, a deep violet shade is produced, which, after washing thoroughly in water, changes to orange. This orange shade again

changes to violet if treated with mineral acids. That the alpha naphthylamine has combined with the silk diazo compound in a position in the ring, and not as a diazo amido compound, is readily proved, as the free amido group can be diazotised by immersion for a few minutes in dilute nitrous acid solutions, and combinations effected with cold alkaline solutions of hydroxy compounds.

With resorcinol, a deep crimson is produced—a shade of considerable beauty. This shade can be further modified by treatment with solutions of iron, cobalt, nickel, copper, and other metallic salts, varying shades of brown and bluish red being produced. Other shades of red are produced by development in alkaline solutions of alpha and beta naphthol, which are further modified by treatment with metallic salts.

The only blue shade I have been able to produce was obtained by the development of the diazotised alpha naphthylamine—silk compound. Combined with amido naphthol di-sulphonic acid H (1:8:3:6) in a slight alkaline solution, a deep greenish blue is produced. Further treated with solutions of ferrous salts, this blue shade is converted into black (or a shade which very nearly approaches black).

Beta naphthylamine may also be employed for development, but the shades produced do not represent the same range of colour or brightness as those produced from alpha naphthylamine.

It is of interest to note that of the colours produced by development with naphthalene derivatives the best ranges of shades are obtained from beta hydroxy compounds and alpha amido compounds.

### An Intermediate Product of the Action of Light.

The silk diazo compound when exposed to light does not appear to change directly to a body incapable of continuing with aromatic hydroxy and amido compounds, but passes through a definite intermediate stage.

By careful observation it is apparent that the yellow diazo compound changes under the influence of the first few seconds' exposure to a pink shade, which then rapidly changes to the cream or buff inactive or undevelopable state.

The pink body produced by intercepting the exposure at the intermediate stage will not combine with aromatic hydroxy or amido compounds, but in the presence of caustic alkalies in dilute solutions gives a brown colour which is permanent.

I am of the opinion that the diazo compound first undergoes intramolecular change, being converted into a nitroso compound, which under the influence of further exposure to light decomposes into what is presumably a hydroxy compound.

Thus:— $X.N:N.OH \rightarrow X.NH.NO \rightarrow X.OH + N_2$ .

It is the nitroso compound which yields a brown colour when treated with caustic alkalies.

In making comparative experiments with Messrs. Green, Cross, and Bevan's Primuline diazotype process, I have observed that fabrics dyed with primuline diazotised and exposed to light pass through the same intermediate stage; if the exposure is stopped at this point and the fabric immersed in dilute caustic alkalies, a dark brown colour is produced.

It would be of interest to learn whether this observation has also been made by Messrs. Green, Cross, and Bevan. Although the results are of no great practical value, this observation can be utilised in the production of photographic prints.

### Modified Methods.

Diazotised silk is exposed under a photographic negative for a very short time, whereby the exposed portions have been changed to the pink or nitroso stage, the unexposed portions remaining as unchanged diazo compound. Immersion in warm dilute caustic soda or potash produces a brown positive print.

Another method of application is to expose the diazotised silk under a photographic positive until the exposed portions are converted to the undevelopable or "hydroxy" stage, the unexposed portions remaining as unchanged diazo compound. A short exposure to light of the whole surface of the fabric converts the diazo portions into the "nitroso" compound. Development in warm dilute caustic alkali yields a brown positive print.

The silk diazo compound is very slightly affected by exposure to

artificial light, hence the operations on sensitising, drying, developing, etc., may be safely carried out in gas light. Prolonged exposure to artificial light, however, converts the sensitive diazo compound to a golden yellow colour which is incapable of development with aromatic hydroxy or amido compounds.

The golden yellow colour is extremely fast to light, and appears to resemble very closely the colour produced on silk by treatment with nitric acid. Samples which I have had exposed to diffused sunlight for several years have changed but slightly.

Having outlined the process, I think it would be of use if I supplied a few suggestions for those who may wish to make experiments in silk diazotypes or serotypes as I think they should be designated.

### Subject.

Dealing first with the subjects which lend themselves to reproduction by the process, it is obvious from the surface of the fabric that subjects depending on very fine detail are not very suitable.

I have found that landscapes depending for their effect on the general scheme of light and shade, and particularly where the contrasts are very marked, give very good results, as the contrasts are always softened to some extent in the reproduction. Water effects and yachting scenes also reproduce admirably; in fact, any broad effect where the slight softening of the contrasts which always takes place does not destroy the balance of the picture.

### Positives.

The positives should be developed to keep the high-lights clear and white, and the photographic developer should be selected with this end in view. I have found that the best results are obtained by employing hydroquinone or hydroquinone and metol. Any developer suitable for photo-process work will give very satisfactory positives. It is essential that the positives should be absolutely "sharp" to allow for the softening effect to which I have already referred.

### Printing.

The time required for printing depends of course upon the light and the density of the positive.

Some experience with the process must be gained before really satisfactory results are obtained, but an excellent method of determining the time of exposure is to fasten a small piece of the sensitised silk on to the printing frame and observe when the yellow colour of the diazo compound has completely changed to the cream shade of the inactive or undevelopable body. In direct sunlight with a positive of ordinary density, about 20 to 30 seconds is a sufficient time for exposure.

### Development.

For the development of prints up to 12 x 10, a beaker or other vessel having a capacity of 200 c.c. suffices, the silk being moved about during the development with a glass stirring rod. From two to three minutes is usually sufficient to complete the development.

Care must be taken not to have an excess of caustic alkali for two reasons:—(1) Injury to the silk fibre may take place. (2) It is sometimes found that portions of the lighter shadows have only been acted upon by the light sufficiently to convert the diazo compound into the nitroso compound. In such cases the half-tones appear as dark browns, rendering the print useless.

After developing the silk should be well washed in water and finally rinsed in a half per cent. solution of acetic acid to brighten the silk fibres and also the developed colours. The fabric should be dried on a frame of suitable size and finally lightly ironed on the back.

The colours produced by this process are very fast to light, especially those obtained by the treatment of the developed colours with metallic salts.

The dark brown produced by development with resorcinol and subsequent treatment with ferrous sulphate is exceptionally fast; patterns which I have had exposed to direct and diffused sunlight for six or seven years remaining apparently unchanged.

They are also fast to boiling water, and boiling in neutral soap solutions has very little action on many of the colours.

Regarding the application of the process, I think there may be some opening in the realms of decorative art. The possibility of producing the photographs of great fastness to light, washing, etc., in shades to harmonise with the general colour scheme of a room, should lead to its adoption for the production of cushion covers, panels, frescoes, etc., and to those who may wish to make experi-

nts in this direction, I may say that the process is not protected, and they are therefore at liberty to apply it in any manner they desire.

To many amateurs, I am afraid the fact that the printing is effected

from positives may prove an insuperable difficulty, but to those students of photography who have taken up enlarging and lantern work the process should be of some interest and value.

FRANK J. FARRELL, M.Sc.

## THE LATENT IMAGE.

(A paper read before the London and Provincial Photographic Association on February 8th.)

The latent image of the photographic plate consists of some alteration of the sensitive surface, so that the silver haloid becomes more readily reducible to metallic silver by chemical reagents, or that the osmit from a solution precipitating metallic silver is directed to parts that have been affected.

Light is the form of energy with which we are more familiar as producing the change, but developable latent images are also produced by many other agencies, notably pressure, X rays, electric discharges, the emanations from radium, wood, and other radio-active substances, and by some chemicals such as stannous chloride. The continued action of many of these agencies, light particularly, produces changes which are visible, as in the various printing-out processes. These actions must be carefully distinguished from the phenomenon of the latent image, which is produced by much lower exposures, and which does not manifest itself before the application of the developer. The chemical changes produced by the continued action of light on silver haloids have very rightly received some considerable amount of attention, because of the possibility of their throwing light on the nature of the latent image. Prolonged exposure of the silver chloride produces a darkening of the compound and an evolution of hydrogen chloride. Now this liberation of chlorine must result either in the reduction of some silver to the metallic state or in the formation of some less highly oxidised compound than the chloride, or an oxychloride. Silver bromide is affected in a similar manner, but in less degree, while the iodide undergoes no change unless mixed with an iodine absorbent. Such changes are accelerated by the presence of moisture and oxygen. Robert Hunt, in fact, considered that he had demonstrated that the latter was essential to the darkening of silver chloride by light, and Meldola and others have suggested that an oxychloride may be a normal constituent of the hardened product, the formula  $\text{Ag}_2\text{OCl}_2$  having been given by Dr. R. Hodgkinson. However, probably the larger number of workers have concluded that sub-haloids are formed, formulae, such as  $\text{Ag}_2\text{Br}$  and  $\text{Ag}_2\text{I}$  being given, sometimes one sub-haloid and sometimes two being assumed to be formed, but in spite of the great amount of work that has been directed to this problem little is known with certainty.

### Sub-haloid Theories.

The hypotheses which have obtained the widest acceptance regarding the nature of the latent image are those which assume an identity between the coloured reduction (or oxy-haloid) products of the continued action of light and the constituents of the latent image. The thesis is that these reduction products are actually formed in the plate in such infinitesimal quantities that they escape detection, but at nuclei which the developer reduces to a metallic state. It is then further presumed that these particles of reduced silver act as centres of deposition, and that the silver bromide in their immediate neighbourhood is then reduced more rapidly than the bromide not in close association with these reduced particles, and that in this manner the negative image is gradually built up.

These hypotheses can only be accepted in proportion to the strength of supporting evidence, and in this case evidence is required, firstly, to the existence of the reduction products in the film; secondly, that the light should act selectively among the silver bromide molecules, only reducing, perhaps, one in many thousands, and leaving the others untouched, and that the number of these reduced molecules should be a function of the light stimulus; and thirdly, why the reduction products should act as nuclei facilitating the deposition of metallic silver under the action of a reducing agent.

Now, the chief basis of support for this class of theory appears to be that chemical reagents act towards the latent image in retarding or accelerating the effect in a similar manner as they do in regard

to the formation of the coloured reduction products. But this may or may not be considered as indicating the identity of the latent image with the reduction products, because, whatever theory was postulated, it would be expected that conditions which tended to help the change which rendered possible the reduction of the silver haloid after short exposure would also help in the same direction when the prolonged action of light was tending to produce reduction changes. And also against this view must be put the complete absence of evidence that anything in the nature of a chemical change has occurred. A chemical product differing in any respect from the constituents of the unexposed film has yet to be discovered.

Of a somewhat similar nature to the sub-haloid and oxy-haloid theories are those which suggest that the latent image is produced by the breaking down of associated molecules of silver bromide, or that it consists of silver grains. Luppé-Cramer considers that the destruction of the latent image of a collodion plate which remains after fixation by nitric action supports the silver grain theory, as silver would, of course, be soluble in that reagent. On the other hand, S. E. Sheppard has recently shown that an oxidising solution of ferric and ferrous oxalates, which bleached negatives and would have oxidised any silver grains, has no effect on the latent image.

Eder, in a recent paper, puts the sub-haloid theory forward as being the most probable, and draws a number of conclusions from the effects of "hypo," potassium cyanide, and nitric acid, but no crucial test of its chemical nature is attempted; this is assumed. I have noticed that in the acid development used in wet-plate work, a sub-haloid is certainly not essential to direct the deposition of the silver. For instance, if a glass plate have an electric spark passed over the surface, the track of the discharge can be developed by the usual iron developer (ferrous sulphate and acetic acid) to which a few drops of silver nitrate solution have been added. The image in this case is built up by silver deposited directly on the glass surface; there is no colloid or haloid present.

Some experiments of Sir J. Dewar, however, seem to render the idea of any chemical change forming the basis of the latent image quite untenable, for he has shown that the photographic plate retains some of its sensitiveness (10 per cent. of the original at  $-252^\circ\text{C}.$ ) at temperatures approaching the absolute zero. Now, the chemical activity of even elements like fluorine practically ceases at much higher temperatures, so that it is not reasonable to suppose that light could produce chemical changes under such conditions.

### Sensitisers.

Substances which have a chemical affinity for the halogens generally act as sensitisers, both as regards the formation of the latent image and also the production of coloured compounds, with long exposures. This would be expected whatever hypothesis concerning the nature of the latent image is postulated, for among the various factors determining the sensitiveness must be the unstableness of the silver haloid, which would be increased by the presence of any body which would readily absorb it, and this would affect the result, whether the latent image consisted in a partial reduction of the haloid during exposure, when the liberated halogen would be absorbed at the same time, or whether it resulted from some physical strain in the molecule. For in this latter case the presence of a substance having an affinity for the halogen would be to increase the ease with which the light produced the molecular change, and so the effect of the subsequent development would be enhanced.

It is, however, interesting to note that there does not appear to be any relation between the effect of a given sensitiser in accelerating the formation of coloured reduction products under the continued action of light, and in increasing the ordinary photographic speed

of a haloid. That there is no similarity between these two actions is a point which has been emphasised by Meldola. There does not appear to be any reason to suppose that a sensitiser is essential to a photographic action, although some such idea must have prompted suppositions of the class that  $\text{AgI}$  may act as its own sensitiser with the formation of higher iodides, because under some conditions silver might be tri-valent. While many substances—gelatine, for instance—may be supposed to act in this way, there does not seem to be any probability that the enormous increase of speed conferred on collodion emulsion by the modern colour sensitising dyes is of this nature.

### Chemical and Physical Actions.

It may be well for us to consider the difference between what may be called respectively a chemical and a physical change. If a compound is resolved into its constituent parts or groups, either to appear as such or to enter into fresh combinations, we say a chemical change has occurred; but if a substance, an elementary one, such as copper, for instance, changes perhaps its electrical resistance, we speak of the change as physical. But we know that no distinct line can be drawn between these changes; a different disposal of the constituents of a molecule produces the different physical properties of stereoisomers, catalytic actions cannot always be explained on purely chemical grounds, allotropic modifications of any element possess different chemical properties, while many cases occur where there is reason to presume the existence of so-called physical compounds between molecules.

These things tend to show that the distinction between a chemical and a physical change may sometimes be a somewhat arbitrary one, and that many changes may occur in the relationship of atoms within the molecule without any definite chemical change occurring. It is possible that the action of light on silver haloids may have the effect of weakening the inter-molecular bonds, an action which in the limit would result in a breaking up of the molecule—a chemical decomposition. We know that electro-magnetic radiation produces many physical changes which are readily detectable, changes of crystalline form, of electrical resistance and potential, and in view of such phenomena it is quite conceivable, in a case where the final action of light is the production of a chemical change, that before this point was reached the molecules would have been changing all their physical properties, and in the case of the photographic image there would, under such circumstances, have to be sufficient internal molecular friction to prevent the recovery of the substance to its initial state upon the expiration of the exposure.

### Molecular Phenomena and the Latent Image.

From the details of purely photographic phenomena let us turn to briefly survey the wider field of effects which are directly dependent on the properties of the molecule. And here the work of Professor Bose may be cited, for he has furnished the first practical demonstration of the identical character of all molecular phenomena, an identity that many had previously expected, and which further work will probably confirm as details are gradually unravelled. Expressed broadly, the generalisation is that all phenomena which are dependent on the properties of the molecule obey the same general laws.

The S-shaped characteristic curve of the photographic plate finds its parallel in all other cases that have been worked out, as with magnetic induction in iron, and the electro-motive changes produced by mechanical stimulus, and by the action of light. Visual luminosity, there is reason to believe, follows a similar law. Among molecular phenomena the time occupied in recovering to the initial state after the cessation of an applied force may vary within wide limits. With some Hertz wave receivers it may be less than one second; in magnetic work there is a partial recovery immediately after the removal of the magnetising force, but complete recovery does not take place without assistance, as with the usual Hertz wave receivers. In Professor Bose's experiments on the electric response to mechanical and light stimuli recovery was generally complete in from one to ten minutes, but in one case complete non-recovery was induced by the action of precipitated calcium oxalate. The latent image must be a case of non-recovery to the normal condition, but it is interesting to note that certain chemicals (nitric acid and potassium

bichromate, for instance), destroy the latent image—i.e., allow the plate to recover to its normal state.

Professor Woods has found that latent images produced by different means have not all the same stability, and that those which produce the more stable effects can obliterate the others. The order of stability was found to be pressure, X rays, a brief light exposure, and lastly, most stable of all, a long exposure to light of low intensity. Professor Woods is of opinion that these facts are opposed to Dr. Bose's suggestion that the latent image may be a molecular strain, but I think it would be easier to argue that they were in agreement with it, for if the light stress produced a physical strain between the molecular constituents it would be expected that this would be more permanent if built up by long continued rhythmic vibrations than when irregular stimuli were applied as with pressure.

Reversal, seen in the case of photography as a recurrent dropping of the density curve with long exposure, occurs in many molecular phenomena. Continuous exposure of a silver plate to light, or continuous mechanical stimulation of a plant or metallic wire, causes the electro-motive force induced to reach a maximum and then decline, while opposite effects, as in Hertz wave receivers, may sometimes be produced by small and large stimuli. In connection with the action of such chemicals as potassium bromide and sodium carbonate in photography, some experiments of Professor Bose are interesting. He found that the electrical responses of metallic wires under mechanical stimulus were affected by the presence of these reagents; the magnitude of the responses being lowered by the restrainer potassium bromide, and enhanced by the accelerator sodium carbonate, and this under conditions that precluded the possibility of any chemical action.

A point of importance in connection with the action of potassium bromide is that it is one of the products of the chemical changes taking place during development, and, as has been recently pointed out by C. E. K. Mees and S. E. Sheppard, development is, under some conditions, a reversible change, negatives being bleached by a mixture of quinine and potassium bromide, in the absence of alkali or alkali sulphite. In this case the quinone was reduced to quinol and the metallic silver converted to silver bromide. And later S. E. Sheppard has obtained the condition of equilibrium, with a mixture of ferrous and ferric oxalates, and has pointed out how this reversibility may account for the induction period observed in development when bromide is present.

The ripening of photographic emulsions is a point of great interest in connection with our subject. The increased sensitiveness conferred on gelatine emulsions by the application of heat or of ammonia is a physical change in the condition of the silver haloid, which finds a strict parallel in many other molecular phenomena. Among these may be mentioned the decrease of magnetic hysteresis in iron by annealing, and the increased sensitiveness and regularity of response of Hertz wave receivers conferred by gentle heating or the application of ammonia. Another case where these two agents have a similar effect is in Dr. Bose's experiments on the electric response of plants and metals to a mechanical stimulus, such as a torsional vibration. In these experiments two pieces of the same metallic wire were mounted side by side in water and connected to a high resistance galvanometer through a megohm. Upon giving one of the wires a torsional vibration a transitory electro-motive force was produced. Now this electro-motive variation was generally small and irregular at first, but by immersing the wires in hot water for a short time and "ripening," or, to employ a more general term, annealing them, the responses became more regular and larger. And, what is perhaps of still more interest to photographers, exactly the same result can be obtained by immersing the wires in weak ammonia, from which they are afterwards rinsed.

Similar phenomena accompany the electro-motive effect produced by light on silver plates, and there is little doubt that the effect is a perfectly general one among molecular phenomena. The phenomenon of ripening, or annealing, would appear to be most probably something in the nature of a reduction of internal molecular friction. The aggregation of silver bromide particles which takes place during the ripening of a gelatine emulsion have generally been considered an essential part of the change, if, indeed, the increased sensitiveness was not directly due to the aggregation. This aggregation, it has been suggested, is due in the case of ripening by heat to the solution

bility of silver bromide in potassium bromide and gelatine, and in case of the use of ammonia to the solubility of silver bromide in that reagent. With either process the supposition has been that silver bromide dissolved from the emulsion is reprecipitated upon the remaining particles. There do not, however, appear to be any sufficient reasons for postulating such a process as solution and reprecipitation to account for the very common phenomenon of the aggregation of precipitated particles into larger and larger masses, which usually proceeds from the time of precipitation, and which is accelerated by heating.

Regarding the electron theory suggested by Professor Joly, I do not feel that there is yet sufficient evidence to say much for or against, but it is not at all impossible, nor even improbable, that the loss of electrons may be the cause of the changes in properties, including change of potential, produced by the action of light on the photographic plate.

And, in conclusion, let me express the opinion that, until much more definite information is forthcoming, we must reject all the chemical theories and look upon the latent image as a physical modification of the silver haloid, accepting Dr. Bose's generalisation of its relation to molecular phenomena and reserving judgment as to the nature of the change.

A. J. BULL.

### VAGARIES OF COLOUR-BLINDNESS.

THE Thursday evening lectures which were so long a justly popular feature of the Camera Club are being continued, we are glad to say, under the auspices of the Blenheim Club, and judging from the attendance last week, when Dr. Edridge Green lectured on "Colour-Blindness," are received with favour by the older members of the "Blenheim." Yesterday (Thursday), the lecturer was Tempest Anderson, who was down to speak on a visit to South Africa with the British Association, and among the forthcoming fixtures are: "Mountain Travelling in the Eastern Countries," by G. P. Baker; "English Royal Heraldry," by Cyril Davenport; and "Morocco: Its Court, People, and Customs," by C. Rider Noble.

Passing now to the subject of Dr. Edridge Green's discourse. It appears that five per cent. of the population are dangerously colour-blind, not so colour-blind that they cannot match colours, but with vision sufficiently defective to prevent them from naming colours. The engine-driver or the pilot has to name his colours, not to match them. On ordinary occasions an engine-driver would not confuse red and green, but if the day were slightly foggy he would call every red light green and every green light red.

Dr. Green suggested that instead of the casual and absurd method of testing colour-vision at present in vogue, consisting of matching pools of various tints which the person who can see only two colours can generally accomplish, there should be a system of testing by means of coloured lights. These lights could be modified by means of neutral glasses, or could be slightly fogged, and in this way their appearance would be altered in the case of the colour-blind, but could remain the same in that of the normal sighted.

Colour-blind people, said Dr. Green, have no difficulty, as a rule, with yellows and blues. The man who is able to distinguish red, yellow, green, and violet, is sufficiently colour-sensitive for the practical purposes of life, while the man who is able to see, in addition to the colours mentioned, orange and indigo has quite exceptional colour perception. The cases in which the colour-sight is so defective at the solar spectrum appears as one tint from end to end are very rare. Men who see three colours never mistake red for green or green for red, while men who see four colours only become confused between the greens and blues.

The questions of the influence of temperament upon colour were discussed. Many creatures, including the octopus and cuttlefish, are sensitive to red, and in photographic work prolonged exposure to red light is harmful, acting upon the nerves as a fatiguing influence, and setting the sense of judgment. It was mentioned that some of Messrs. Lumière's workpeople had complained of ill-effects ensuing from working in red light.

Every child, said Dr. Green, comes into life colour-blind. The first two colours that he sees are black and white, and the perception of red and violet comes later on. Of men of various races who have worked under him as art students, said one speaker, the Japanese

were invariably the most accurate in their colour-sense. This might be due to a native sensitiveness to colour, but more probably it was due to the habit which the Japanese had of noticing trifles. In fact, says Dr. Green, the power of colour-perception is intimately bound up with the power of general observation. This is not to say that colour-blind people are unintelligent, but the fact remains that a colour-blind person can get along almost as well as a normal-sighted one if he will "take notice." The case of a colour-blind man who was an expert artist in black and white was mentioned. His shading was always accurate because he employed his powers of observation, and coloured objects had for him "a black and white expression which conveyed an accurate impression of colour." There is no defect, says Dr. Green, in the eye of a colour-blind man; the defect is in the colour-perceiving centre in the brain. Thus many forms of brain disease bring on colour-blindness.

The lecture was illustrated by a series of lantern slides showing side by side a coloured original and the copy of it made by a colour-blind person. In some instances, we believe, the slides were three-colour, reproduced by the Sanger-Shepherd process.

### THE INTERNATIONAL CONGRESS OF PHOTOGRAPHY.

THE resolutions adopted by the above Congress at its meeting in July last year have just been published. The following is an abstract:—

The standard light is to be the acetylene lamp as devised by M. Fouché, or the Fery-Monpillard lamp (see B.J. Almanac, p. 724). Further experiments are to be undertaken to establish the ratio of these with the Violle unit, and it is suggested that a photographic comparison should be made. The unit is to be the quantity of white light falling upon a square centimetre at a distance of one metre from the acetylene lamp, which is equivalent to 1.20 of the Violle unit. This is to be called B.P.M.S. (bougie photographique-mètre-seconde). The transparency of a deposit, examined by transmission, is the ratio of the quantity of light-transmitted to the quantity of light received. Opacity is the inverse of this ratio, and density is the logarithm of the opacity. The unit of density is that which transmits one-tenth of the light received.

The normal duration of development is such that with the density of 7 the densities should be proportional to the logarithms of the quantity of light transmitted by the negative and inversely proportional to the quantity of light received at the moment of exposure. The Congress admit that plates should be tested with the developer recommended by the makers, and recommend that makers should give on the box labels the formula and temperature of the developer.

The sensitiveness of an emulsion should be the quantity of light necessary to obtain the unit of density with normal duration of development. The latitude of an emulsion should be the interval where the densities, with normal development, remain proportional to the logarithms of the quantity of light, and should be expressed by the differences of the limiting densities. Every emulsion should be designated with its sensitiveness, its latitude, and its fog, the latter being the density obtained with normal development without exposure to light.

Orthochromatic plates should be designated by their maxima and minima of sensitiveness, and by the wave length on the less refrangible side where the sensitiveness practically ends. The sensitiveness to white light and their chromatic sensitiveness should be stated.

Formulae for colour-filters or screens should be given in specific weights of the colouring matter per square centimetre of surface, and the liquid filters should be one centimetre internal thickness. In all cases of organic dyes the names of the makers, the trade names and marks of the dyes should be given.

The Congress suggests that makers of optical glass should come to an "entente" to do away with the confusion now existing in the nomenclature of glasses, and that four groups should be made, or that, if this be not possible, the glasses should be divided into two

classes, using the usual notation  $v = \frac{D-1}{F-C}$ , and that all glasses with this power above 50 should be classed as "crowns," and all others as "flints."

Diaphragms are still to be numbered on the *f/x* solution, but the word "diameter" be substituted for "aperture." Experiments are to be undertaken to prove the loss of light by absorption and reflection, and some attempt should be made to determine a characteristic co-efficient. Shutters are to be marked with their speeds with an error of only 5 per cent.

The Congress recommends that photographic sensitive preparations should be passed by the postal authorities as samples, provided they bear the makers' labels and bands unbroken. Every maker should see that packets of his preparations bear such bands, and the label of a black star on a red ground which is recognised by the Customs authorities. It further suggests that postal authorities should admit photographs and works illustrated by direct photographs on the same terms as any book or magazine illustrated by a photo-mechanical process. Further, that the postal authorities should admit, on the usual terms, postcards illustrated by the photographs mounted thereon. Cinematograph films, when enclosed in metal boxes, should also be passed by the postal authorities as "samples."

## Photo-Mechanical Notes.

### Carl Hentschel, Ltd

The annual general meeting of the Carl Hentschel, Ltd., was held on February 22, when the chairman (Mr. Carl Hentschel) reviewed the progress of the company and submitted a scheme (which was approved) whereby the three branches of the Carl Hentschel business, Carl Hentschel, Ltd., the Meisenbach Co., and the Hentschel Colourtype, Ltd., are to be amalgamated into one company with a capital of £130,000. It was pointed out that the business of the companies has expanded enormously during the past few years—the net profits of the three concerns for the past two years averaging £10,191—a sum sufficient to pay a dividend of 6 per cent. on 60,000 preference shares, and 8 per cent. on 50,000 ordinary shares.

The history of the Carl Hentschel in "process" is quite one of the modern romances of industry. The facts are probably known to those intimately connected with illustration, but may be recalled on the eve of the firm's important new developments:—

In 1880 Carl Hentschel, then a lad of 16, was manager of one of the few photo-etching studios in London.

In 1887 he started in business for himself with six hands.

He next acquired the process of George Meisenbach, the founder of the modern half-tone process, which then became part of the Hentschel business.

Colour engraving has been added to the methods prosecuted, and the Hentschel Colourtype works at West Norwood is now possessed of processes which enable it to compete with and beat the German producers of colour printing.

These several processes of reproduction have been applied in many important commercial directions, chief among which the firm includes newspaper and magazine illustration, catalogues and illustrated books. The Colourtype process in particular has been taken up by publishers, as witness A. and C. Black's series, "Beautiful Books of Travel," and Heinemann's recent "Rip Van Winkle." Messrs. Hentschel likewise specialise in the illustration of catalogues in colours, and a prospectus which they have just issued shows what their process is capable of in the way of placing before the purchaser an actual facsimile of an article. In journalism also the "Colourtype" bids fair to show the way in magazine production just as the half-tone in newspapers has followed the first use of Meisenbach half-tone blocks in the "Daily Graphic." Thus the whole outlook for the Hentschel concerns under their centralised control seems extremely promising.

It may be added that two large screens of Messrs. Hentschel's colour work will be on view at the Southampton Convention.

### Fire at a Photo-Engraver's.

Last week a fire (the cause of which is unknown, but which was attended with disastrous results and damage to the extent of between £2,000 and £3,000) occurred at the premises of Messrs. André and Sleigh, photo-engravers, Bushey Grove Road, Bushey. The outbreak assumed serious proportions, for four or five departments were

gutted, including the negative store-room, the copper and zinc etching department, and the mounting and engraving rooms. The property and contents were insured.

### Three-colour Lithography.

According to the recent patent No. 5,473, 1905, taken out by Sir Joseph Causton and Sons, Ltd., and W. G. Meredith, a modified procedure is adopted in the making of negatives for printing in three or more colours by half tone lithography or other processes. For this purpose continuous tone negatives are first obtained, as usual, the use of lined or grained screens being dispensed with at this stage. From these negatives positives are printed upon roughened opal glasses or like surfaces suitable for drawing upon. The necessary corrections are then made to these positives. From these corrected positives half-tone or grained negatives are then taken and the process is completed in the ordinary manner. The invention is not limited to lithography, but is equally applicable to other printing surfaces.

## Exhibitions.

### BIRMINGHAM PHOTOGRAPHIC SOCIETY.

On Saturday, February 24, the twenty-first annual exhibition of the Birmingham Photographic Society was opened by Sir Benjamin Stone, M.P., a former President of the Society. Sir Benjamin congratulated the members on the very fine collection of photographs in the rooms, and pointed out how fortunate they were in having the beautiful galleries of the Royal Society of Artists at their disposal. He urged every member of the Society to bear in mind that belonging, as they did, to one of the leading associations of the country, it was their duty to emphasise the educational side of their work, and to do all in their power to suppress the vulgarity of photography as practised by the "camera fiend" in catching and publishing unauthorised "snapshots" of all and sundry. But he did not wish them to suppose that he would condemn snapshots, because it was possible to secure many things which could be obtained in no other way. The thanks of the meeting to Sir Benjamin and Lady Stone for their presence were happily expressed by the President, Mr. Howard J. Collins, and two of the Vice-presidents, Messrs. Shirley Smith and Thomas Taylor.

Mr. Lewis Lloyd, the hon. secretary, is to be congratulated on having surpassed all previous successes, for we have no hesitation in describing the exhibition as the finest that has yet been held in this country. Apart from much excellent work from British workers, the extraordinarily beautiful pictures sent from abroad would make any exhibition memorable. Nearly one hundred and fifty photographs have been sent from abroad, and the fact that they come from Spain, Denmark, France, Germany, Russia, America, Italy, and Hungary, spontaneously and without invitation, is a great compliment to the Birmingham Society. The judges in the Pictorial Section must have had an extremely difficult task, and we must confess that we do not agree with the bestowal of the awards in any one case, except in the Novices' Section.

In the Open Section a silver medal has been given to 111, "Portrait" by Alfred Ornano, a weak platinum or bromide with a palpably artificial lightening of the head and its surroundings; it is quite incomprehensible what special merit can have been discovered in this poor, feeble print, which is surrounded by at least a dozen superb pictures by Edoardo Garrone. Among them 120, "Bobo and Bebe," a young woman nursing a child, is perfect in its rendering of tones. 110, "Dolorosa," the figure of a melancholy woman, is almost as good in the same way, but the subject is not so pleasing. 113, "Torrissio de Sole," is a most audacious but quite successful attempt in rendering strong effects of light and shade—a little peasant boy, with a merry smile, is standing on a stool so that his head and shoulders are flecked with sunshine from a window above. 116, "Quieto Vivere," two girls in peasant costume, peeling fruit, would be considered excellent were it not eclipsed by others around it. 112, "Flora Montano," is another example by the same Italian worker—a group of three peasant girls in a wood; the effect of sunshine through the trees

and on the stream is most beautiful, and the grouping of the figures beyond criticism. The most striking feature of Edoardo Garrone's work is its perfect technique, and proves a fact which we have always maintained—that good technical work does not mean bad art. The same may be said of the eighteen photographs by R. Dürkoop, of Hamburg, whose work displays the same technical quality, and is no less pictorial in effect. The exhibition of such work ought to dispel the nonsense that is talked about good, clean photographic work being unable to produce artistic effects. 305, "Bildnis einer Dame," receives a medal, and it is a beautiful portrait of an old lady; but the hand on which the face is leaning appears too large, an effect which might have been avoided by a slight turn of the wrist. We prefer 308, "In der Dämmerung," or 302, "Lecture," the first, a lady and gentleman sitting near a window, all in low tones except a few gleams of light catching the lady's hand and dress; the second apparently the same models, the lady holding a book; the scheme of lighting is different, but equally pleasant. 304, "Verzückung," a full-length of a lady, with parted lips and closed eyes, gains a silver medal; but, although the poses, lighting, and general effect is excellent, there are several others by this worker to be preferred. 315, "Der Lampion," shows the versatility of the photographer. We look through a doorway into a sunlit garden with a child playing with a lantern. The effect is very quaint and pleasing. 303, "Im Kinderzimmer," is a group of three children looking at a large ball; although the children are cleverly arranged, and the technique is admirable, the result is not quite so successful as others around it, for it suffers by comparison with others by the same hand. 311, "Bildnis Zweier Herren," an unconventional group of two gentlemen, shows splendid rendering of textures.

The French photographers are well represented by R. Demachy with his "Motor Race," and several portraits in his well-known manner; by C. Puyo, Detaille, and by several whose names are new to us. 290, "La Forêt Enchantée," by A. G. Gimeno, is a most dainty bit of forest scenery, after the style of an old engraving, but it suffers by the imitation of the decorative title at the bottom of the photograph. 321, "Geese," by Chas. H. de Nagyrev, a study of geese with very strong effect of sunshine and shadows, receives a bronze medal. 319, "Moonlight," by the same, is a fine effect of sombre effect in gum, but marred by the introduction of the stars in the sky.

There is some fine work from America: dignified portraits, and 351, by Dudley Hoyt; two superb winter scenes, 340 and 341, by C. G. Dudley; and among many other interesting pictures several showing great variety by E. N. Sewell, of San Francisco; "A Portrait," a delicate head of a lady against a white background; 354, "The Man in the Boat," just a little bit, with nothing but a man in a boat and its reflection in the water, yet together charming; and 359, "A Foggy Morning in a Japanese Garden," one of the daintiest and tenderest things in the exhibition.

It is interesting to notice how the English exhibitors fare beside the wonderful work of the foreign schools. Perhaps the only one who holds his own is Arthur Marshall, whose "Dusty Day," 177, is equal to anything in the galleries; 263, "Sundown," a strong, and landscape, is very fine, but the red colour seems scarcely suitable to the subject. J. M. Whitehead has several good landscapes—"On the Clear Winding Devon," is fresh and dainty, while "Nightfall on the Moor," is strong and vigorous, and well suited to the title. W. T. Greatbatch shows several picturesque views in Normandy, printed in multiple gum, not for competition. We welcome his new departure—they are all excellent. Smedley Aston shows several portraits, landscape and architectural views, but none of them are equal to what is expected from J. Cruvys Richards shows a sad falling off, of which doubtless no one is more conscious than himself. It is evident that he has been too busy in other ways to do himself justice. 233, "Portrait," in gum of several colours, is not convincing; the colour of the face is livid, and suggests a model just recovering from a terrible assault. The result does not repay the labour spent upon the work. Mr. G. A. Barton gains three awards, two in the Members' class and one in the Open. No. 71, "Martha," which takes a silver medal, appears to be a Salvation Lass, but the head-dress is completely lost in the intense black of the background, and the drawing

of the face is spoiled by the straight line of black shadow on the left cheek, cutting off a piece of the face and giving a very lopsided shape. 66, "La Joie de Vie," takes a bronze medal, in spite of the fact that it is false in lighting and tones; the background is from a painted landscape, but the trunks of the trees are so dark that they come far in front of the figure, and should have been very much toned down; although the background is intended to represent open air the lighting of the face is that obtained in an ordinary room, with black, heavy shadows. 225, "St. Ursula," is the model and the sort of thing we have seen before too often. Three or four years ago Mrs. Barton leaped into fame, but we must say, "more in sorrow than in anger," that she has made no advance since. No. 17, "Miss Muriel Hampson," shows the "faults of her qualities" to a marked degree. The shadow on the cheek is as black as the deepest shadow in the black hair, and the hand in the left bottom corner is so dark that it might have been encased in a black glove. In the three, 64, 66, and 71, the grouping of the frames shows the sameness of the posing in an almost painful way. In the West Room is a special group of fifty-eight by the same clever lady, but in many the defects of the forced lighting and over-printing are very evident. James C. Batkin well fulfils his promise of last year, and has several excellent prints in gum, showing an appreciation of sparkling light and feeling for fresh, open air, most welcome in these days of murky prints; 259, "A Rift in the Fog," is a capital street scene, but would be greatly improved by trimming off the waggon on the left side. It is always pleasant to welcome a newcomer in the front ranks, and E. D. Taylor is to be congratulated on his work this year; he has made a decided advance in 52, "Sand-dunes"; 22, "Winter"; 30, "Mid Snow and Ice"; and 20, "Sunset." W. A. Clark keeps up his reputation for pictorial architecture, and in 169, "A Norman Procession Path," is the best he has exhibited, and shows strength and restraint. The portraits and figure studies by Ernest A. W. Moore are at first sight rather striking, but show too much effort and striving after effect, and in 87, "Summer Moon," the moon is very palpably put in by hand.

Rev. H. R. Campion shows several of the careful and charming interiors we always associate with his name, and in 242, "Lux Benigna," has caught an effect of bright sunshine in a cathedral aisle most difficult to render. Dr. Grindrod's work, with its murky tones of short range, suffer by comparison with the foreign workers, who secure such a long scale of tones, from bright light to deepest shadow. Arthur Smith's (241) "The Haunt of the Bee" is a grand piece of landscape, with strong, rich foreground of gorse and hemlock, and distance receding right away to the horizon. J. C. Warburg sends very much what we should expect from him, but 217, "Surf," is delightful in its feeling of bright light and rushing water. Miss Warburg's "Valley of Mists," 147, is very charming, and gives the clean white mist of the country—how different from a "London particular"! 161, "Until the Day-break," by S. G. Kimber, is a good rendering of sunshine in a cathedral retrochoir, with rays of sunshine lighting up a tomb, but the effect of light and shade might be a little stronger.

Fred Judge sends some beautiful landscapes. 166, "October," shows a fine effect of sun streaming through clouds, while the foreground and church tower are in shadow; in 193, "An October Evening," we see the same quaint church tower from another point of view—in a tender veil of mist.

The centre group consists of six of Alexander Keighley's magnificent pictures.

The exhibition contains so much fine work that it is impossible to mention more than a tithe of those that merit notice. We would urge all who can do so to visit the exhibition, which remains open till Monday, March 5.

It is pleasant to notice that the sales already amount to a considerable number; in some cases half-a-dozen duplicates have been ordered.

#### BOWES PARK PHOTOGRAPHIC SOCIETY.

A most successful exhibition was held for the last three days of last week by the Bowes Park Photographic Society, which, although only four years of age, has brought together a collection of members' work numbering 250 items, which is surely quite a record in the annals of

a photographic society. Whether this success is to be taken as proof of the assiduity of the Bowes Park members or of the ease with which a certain knack of turning out what is currently accepted as "pictorial photography," we cannot say. At any rate, the show is a triumphant success for so young a society, and contains some very creditable work. Mr. H. C. Bird's "A Street of the Past" (No. 11), and "Lingering Light" (No. 35), both gum prints, are good work, and show that a painstaking worker can use the gum process and resist the temptation to smudginess. C. S. Carr is likewise successful in "The Barge" (No. 90), and in "Evening Rays" (No. 187), where he uses carbon. "Westminster Towers" (No. 66), by A. E. Warner, approaches an oft photographed subject in a new way. There are other photographs which deserve special words of praise, but our space does not allow of further notes, except a concluding one, to congratulate the Bowes Park Society, and to hold it up to others as an example to follow.

#### EDINBURGH PHOTOGRAPHIC SOCIETY.

On Saturday the annual exhibition of this society was opened in their rooms, 38, Castle Street, Edinburgh, and will remain open until the 10th March. The 264 entries crowd one another on the walls so that taste in hanging is at a discount, the effect being somewhat of the nature of a patchwork quilt. John Hepburn, Glasgow, gains the blue ribbon, the Blanc Prize, with "The Wee Invalid," as hung at the R.P.S. The advent of Rudolph Duhrkoop, Hamburg, is a decided gain to the show, his work showing distinct "quality." One of his R.P.S. pictures, "Bildnis des Dichters, Gustav Freussen" — a simple but telling specimen of portraiture — is medalled. Other medalled pictures in the open class (150 entries) are "The Ghetto, Prague," by Miss Winifred H. Aitchison, Oxford; "Tugging Home," Wm. Clayden's (Plymouth) well-known picture; "The History of many a Winter Storm," by John M. Whitehead, which we noted at the Scottish Salon — a masterpiece of pictorial simplicity. "October," one of Fred Judge's (Hastings) series of "month" pictures. Miss Warburg and J. C. Warburg have some characteristic pictures; Miss Gertrude Aitchison shows "Flood," and Dan Dunlop, "The Village Preacher," both as reproduced in the R.P.S. catalogue; John Moffat, Edinburgh, shows "The Dance"; J. Drummond Shiels shows two portraits; Robert Dykes has evidently specialised in "night" photography with decorative aims in view. Many other known photographers are represented, but it is surely unusual for an E.P.S. exhibition to pass without any "open" awards going to Edinburgh; this is the first time I can remember such a state of affairs. What has come over Crooke, Patrick, Johnstone, Auld; their absence is noticeable. In the members' class there are 114 entries, and four medals are awarded, as follows: The President, J. Tudor Cundall, B.Sc., with "A Cottage Home"; "The Curfew Hour, Hexham," by Henry S. Harrison, is an effective "soft" picture, quite carrying out its title; "Finishing Touches," by Mrs. Mary Cooper, and "On Holiday Bent," an unconventional picture of a passenger train discharging its freight, by Charles McKean. Honourable mention is gained by D. W. Thomson, Thomas Kent, and Charles G. Thornton. A series of three lectures has been arranged. Messrs. J. Craig Annan, W. G. McGeorge, A.R.S.A., and Archibald Cochrane were judges.

THE Eastman Kodak Company, of New Jersey, announces the usual quarterly dividends of  $\frac{1}{4}$  per cent. (being at the rate of 6 per cent. per annum), upon the outstanding Preferred Stock, and of  $\frac{1}{4}$  per cent. (being at the rate of 10 per cent. per annum), upon the outstanding Common Stock, payable on April 2, 1906, to stockholders of record at the close of business on the 28th February, 1906.

PHOTOGRAPHIC Survey and Record of Surrey.—The annual meeting (open to the public) will be held in the Lecture Hall, Public Library, Kingston-upon-Thames, at 3.30 p.m., on Saturday, March 10, 1906. The President, Viscount Middleton, will give an address, and the report of the council and the accounts of the year ended December 31, 1905, will be submitted. Arrangements have been made for an exhibition consisting of a representative selection from the 2,000 prints already in the survey collection, in the Art Gallery, Public Library, Kingston-upon-Thames. This will be open on the day of meeting until 9 p.m., and again during the following fortnight until dusk. A short lecture, illustrated by lantern slides, will be given on each Saturday evening, at 8 p.m.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between February 12 and 17:—

DISHES.—No. 3,479. Improved non-spillable dish used in photographic work. Lewis William Donne, 181, Upton Lane, Forest Gate, London.

COLOUR PROJECTION.—No. 3,766. Improvements relating to the optical projection of coloured images. Benjamin Jumeaux, 7, Southampton Buildings, Chancery Lane, London.

COLOURED PHOTOGRAPHS.—No. 3,822. Improvements in coloured photographic pictures. Carl Pietzner, 51, Deansgate Arcade, Manchester.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

DEVELOPERS.—No. 9,537, 1905. This invention relates to the manufacture of a photographic developer from para-oxy-phenylglycinamide.  $\text{HO.C}_6\text{H}_4.\text{NH.CH}_2.\text{CO.NH}_2$  ( $\text{HO.NH.CH}_2.\text{CO.NH}_2 = 1:4$ ), for which purpose this compound is well fitted by its energetic action and by the fact that it yields clear and clean images. It is not necessary to mix it with caustic alkali in developing, alkaline carbonate sufficing to bring out its developing energy; nevertheless, an alkali may be used if desired. Alkaline solutions of the new developer can be kept for a long time without loss of developing energy. For use as a developer the compound may be supplied in an isolated condition or with suitable admixtures, and as a solid or in solution; or may be made at the time it is required for development. The following are examples of the methods of making up the developer:—(1) With potassium carbonate and sodium sulphite: One part of para-oxy-phenylglycinamide is dissolved in 200 parts of water with the addition of five parts of dry potassium carbonate and five parts of anhydrous sodium sulphite. (2) With potassium meta-bisulphite: One part of para-oxy-phenylglycinamide is dissolved in 200 parts of water with the addition of three parts of potassium meta-bisulphite and of six parts of dry potassium carbonate. (3) Concentrated developer. One part of para-oxy-phenylglycinamide is dissolved in ten parts of water, and this solution mixed with a solution prepared by dissolving 3–4 parts of anhydrous sodium sulphite, together with 3–4 parts of dry potassium carbonate in twenty parts of water. In using such a concentrated developer for developing, ten parts are to be diluted with 50–60 parts of water. C. D. Abel, for Actien-Gesellschaft für Anilin-fabrikation, Berlin.

THREE-COLOUR CAMERA.—No. 4,874, 1905. The invention consists in a photographic camera for taking three-colour photographs or ordinary photographs as required, the changing of the plate and the colour-filter being effected simultaneously and mechanically by pressing a spring knob or by pressing an air ball. A disc is employed fixed to a spindle and provided with three-colour filters and with a circular aperture which serves only for ordinary photography; this disc is also provided with pins which serve to momentarily stop the colour-filters behind the objective by coming in contact with a double detent or escapement comprising an upper tooth carried by a level turning freely on a pivot and having its free end abutting against a pin under the action of a spring. The escapement further comprises a lower tooth forming part of a second lever which can pivot upon the first lever, the small arm of this lever being provided with a slot in which is engaged the stem of a screw which is eccentrically fixed upon the pivot of the first lever. This method of mounting the second lever allows of further separating the two teeth by turning a knob when requiring to take ordinary photographs. The filter-carrying-disc is actuated by a spring placed in a barrel and which can be set up by turning a knob or handle mounted upon a spindle on which is fixed a toothed sector which gears with a pinion fixed to the disc. The toothed sector is provided with

three pins, the first of which is designed to act upon a pivoted bar which closes the shutter at the required moment; the second acts as a stop to an anchor-shaped piece, serving to limit the action of the spring according to whether it is required to take three-colour photographs or ordinary photographs; and the third is designed to transmit the movements of the toothed sector to the changing mechanism of the plates which must work simultaneously with the changing of the colour-filter. In order to allow of varying the duration of each operation the power of the spring can be moderated as required by means of a brake formed by a metal strip held at one end by a screw, and the free end of which can be raised or lowered by turning a knob, the stem of which is a screw, which, by screwing into the strip, causes more or less pressure upon the point of the spindle on which is fixed one of the ends of the spring. The plates are placed in metal frames having on their lower edges projecting pins located between a lower angle bar and an upper plate. These pins are seized by the teeth of rocking bars when the filter-carrying-disc turns one division and a photographic plate has at the same time to be changed. When requiring to take three-colour photographs the apparatus is set by turning the knob of the barrel-spring, the bars being turned upwards. When the knob for lifting the levers is pressed the third lever is raised and carries with it the two other levers; the first movement, which is produced in the rotation of the shutter which exposes the lens under the action of a spring, the said shutter being no longer retained by the pin on the third lever. The second movement is the passing of the colour-filter behind the lens, the first pin on the disc having passed between the teeth of the escapement whilst the uppermost ratchet teeth of the rocking bars change the first plate by causing the pins on the plate-frames to slide over the inclined planes in order to lay this plate in the bottom of the apparatus. To expose the second plate behind the second colour-filter the knob is pressed a second time and the second plate is changed by the second ratchet teeth of the rocking bars. The knob is pressed a third time in order to expose and change the third plate. J. E. Bousfield, for Société du Photochrome, of 4, Rue de Stockholm, Paris.

## New Apparatus, &c.

Thornton-Pickard Cameras: "Imperial Triple Extension," "Imperial Perfecta," and "Imperial Focal-plane Two-Shutter." These three cameras have been designed and brought out by the Thornton-Pickard Manufacturing Co. in response to the demand for cameras possessing every possible movement and yet offered to the public at a moderate price. We do not have to go back very far in our recollections to a time when such facilities in camera construction were undreamt of except in apparatus of the most expensive description, and not in all of those. Stage by stage the perfection has been reached in which the man with 70s. in his pocket can command the luxuries of camera construction. The Thornton-Pickard Co. will not plead guilty, we are sure, to having inaugurated an era of low prices, but such being the demand of the trade, they are girded their loins for the battle and set themselves to produce an instrument which was as good as their experience in high-class camera construction could make it. Hence the cameras we have described above, and hence our task of describing what they will accomplish.

The "Imperial Triple Extension" is sold as a set, which costs, in half-plate size, 70s. The set includes:—Camera, 1 double slide, lens at  $f/8$ , T.P. time and instantaneous shutter, three-fold stand. The specifications of the camera would fill a column of the "B. J.," therefore we will attempt compression in the hope of bringing facts more directly before the reader:—

Long extension, 21 inches.	Swing back.
Short " 3 "	Swing front.
Rising front	Hinged front.
Falling front	Wide front and bellows.

A noteworthy feature of the camera is the use of spring stretchers which automatically secure back or front squarely with the baseboard when the camera is being set up, or after either back or front have

been moved out of position. The adjustment makes for rapidity and certainty in practical work, and the same remark can be made of many inconspicuous features of these Thornton-Pickard cameras; the movements are not merely a show list of accomplishments of doubtful utility, but are evidently designed from practical conclusions

of what a camera should be for daily use. The shutter is the T.P. Time and Instantaneous, exposing from 1-5th to 1-90th of a second, and giving prolonged exposures of any length. The lens is the Beck symmetrical, working at  $f/8$ , or for 5s. extra the new T. P. "Pantoplanat" can be had, a lens of which we have reason to give an excellent account, and which is evidently worth the increased price. However, we are now speaking of the whole outfit, as priced at £3 10s., and we must characterise it as extraordinarily good value for the money, and a tribute to the factory organisation of the company which is enabled to produce it.

The "Imperial Perfecta" is in most respects the counterpart of the "Triple Extension," but it has an independent rising front, for effective use at very short foci, an extra wide front and bellows,

and a focussing movement with extra rack and pinion for the back of the camera. It is, in fact, the "Triple Extension" with these added qualifications, and the price of the set in half-plate size, with Pantoplanat lens, is £4 4s.

The "Focal Plane Two-Shutter" camera completes the series. It is the Thornton-Pickard embodiment of a focal-plane shutter built

as the back of the camera. With this special exception it is a replica of the "Triple Extension," and its price is but 95s. in the half-plate size, or £5 with Pantoplanat. The focal-plane shutter is a slightly

modified form of the well-known Thornton-Pickard instrument. It has a slit of fixed width, and is made to permit of exposures up to 1-500th of a second. The blind shutter on the front, as before, supplies exposures from 1-15th to 1-90th.

## New Materials.

T. and M. Matt Albumen Papers. Sold by L. Trapp and Co., 8 and 9, Chiswell Street, London, E.C.

In these papers the makers have associated a matt surface with the qualities which are familiar to users of albumenized paper. Yet the finished prints before us do not suggest albumen paper in the least, having, in fact, the appearance of prints on plain paper, and permitting of treatment which only a paper innocent of a colloid coating could be expected to withstand. The paper prints with about the rapidity of P.O.P., but tones in considerably less time. In a gold bath with acetate and carbonate (one grain of gold in 20 grains of water), it gives excellent warm brown tones. In a platinum bath made up with phosphoric acid, a fine range of tones from sepia to cold black are readily obtained, and accord well with the fine velvety appearance of the prints. The paper is obtainable in three grades, one on a thin Rives paper, another on a so-called "Bütten" paper of pleasing banded texture, and another on a stouter and coarser paper of a cream tint. Such are the samples we have used and the selection in our judgment, is one which should meet all the varied requirements of matt papers. The T. and M. papers are sold also as postcards, and perhaps the best advice we can give is the purchase of a shilling sample half-plate packet, which will enable the reader to see for himself the claims which it has upon his notice.

## CATALOGUES AND TRADE NOTICES.

FALLOWFIELD'S clearance sale being an annual event, at which many of an economical turn of mind make a point of picking up some piece of apparatus which is none the worse for being shop soiled, it may be well to note that the sale commenced on Monday last and is continued for three weeks. The price lists disclose an immense variety of apparatus and materials offered at reductions which are one-third and less the original prices. The miscellaneous bargains run to nearly 2,000, and, in addition, the firm offers 500 job lots of mounts. We should state that damaged goods are so described, and that Mr. Fallowfield pays carriage on goods over £5.

THE Northern Exhibition (Manchester).—The prospectus for this exhibition is now ready and is being sent out to all known exhibitors. It may be had upon application to Mr. G. M. Morris, 9, Chandos Road, Chorlton-cum-Hardy, near Manchester. Exhibitors should note that entry fees for pictures not hung will be returned, and all the pictures sent in will be submitted to the judges. As is usual with the Northern exhibitions, a fine illustrated catalogue will be issued. Exhibitors sending in pictures early will have the best chance of their pictures being reproduced.

THE Worthing Camera Club holds its annual exhibition on March 27 and 28. The open classes are for (1) prints, and (2) lantern-slides, and silver and bronze plaques are offered. The secretary is Mr. E. F. H. Crouch, 11, South Street, Worthing.

DURING a performance at the Pavilion Music Hall, Leicester, last week, a cinematograph film in the lantern ignited and caused some alarm, but the flames were extinguished at once, and the entertainment concluded as usual.

A SOCIETY for Hanley (Staffs.).—A meeting was held last week in the rooms of the Young Men's Christian Association, Hanley, for the purpose of forming a photographic society. There was a good attendance, and many of those present expressed themselves in favour of the proposal to establish a society. Mr. C. A. Leech and Mr. F. R. Cox were appointed secretaries pro tem.

THE Photographic Convention.—In addition to other novelties in the way of colour-photography, including the new Lumière process, to be shown at the Southampton Convention, we learn that the cinematographic projection in colours of Captain Lascelles-Davidson is to be shown on a large scale by Captain Davidson and Mr. Friese Greene.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
2.....	Aberdeen Amat. Photo. Assn.	"The Artful Dodger." Mr. Ford.
2.....	Colne Camera Club .....	"Practical Bromide Enlarging." Demonstrated. Mr. J. J. Hartley.
2.....	Bromley Camera Club .....	"Bayeux Tapestry." Illustrated. Rev. H. Bedford-Pim.
2.....	Sutton Photographic Club ....	"Reminiscences." Mr. G. W. Bradshaw.
2.....	Watford Photographic Society ..	"Gum-Bichromate Printing Process." Mr. J. G. S. Munro, F.R.P.S.
3.....	South London Photo. Society ...	Seventeenth Annual Exhibition.
5.....	Southampton Camera Club .....	"Pictorial Photography from the Practical Side." Illustrated. Mr. A. Horsley Hinton.
5.....	Dewsbury Photo. Society.....	Yorkshire Photographic Union Invitation Portfolio.
5.....	Scarborough and Dis. Ph. Soc.	"Platinotype." Demonstrated. Rev. J. Beauland, M.A.
5.....	Catford & Forest Hill Ph. Soc.	"Stereoscopic Photography with a Single Camera." Mr. E. Large.
5.....	Wallasey Amat. Photo. Soc. ....	Lantern Slide Competition for Members only.
5.....	Wandsworth Camera Club .....	"Focus Priz." Lantern Slides—"Stories without Words."
5.....	Bowes Pk. and Dis. Ph. Soc. ...	Fifteen Minute Lecture Competition.
5.....	Leek and District Photo. Soc. ...	Lantern Night. Miscellaneous Slides.
5.....	Heaton & Dis. Camera Club.....	"Amateur Photographer 1905 Prize Lantern Slides."
6.....	Royal Photographic Soc. ....	"Prints in Natural Colours by Platype Process and with Superimposed Carbon Tissues." Demonstrated. Mr. E. J. Wall, F.R.P.S.
6.....	Stafford Photographic Society...	"Tele-Photography." Goerz Lecture.
6.....	Gloucestershire Photo. Society ..	"Winchester Cathedral." Mr. S. G. Kimber.
6.....	Cardiff Windsor Amat. Ph. Soc.	Set of Slides Illustrating Isle of Man Scenery.
6.....	Darlington Camera Club .....	"Toning Bromides." Mr. W. T. Bailey.
6.....	St. Helens Camera Club .....	Exhibition Meeting.
6.....	Nelson Photo. Society .....	Y.P.U. Lantern Slides.
6.....	Sheffield Photographic Society ..	Lantern Lecture. The President.
6.....	Rotherham Photo. Society .....	"Portraiture." Mr. Harold Baker.
6.....	Colne Camera Club .....	"An Evening with the Microscope." Mr. J. Duckworth.
6.....	Halifax Camera Club .....	"Some Uses of the Camera." Mr. S. Sugden.
6.....	Birmingham Photo. Society. ...	"Zigo and Carbon Tissue." Demonstrated. Messrs. Thos. Illingworth.
6.....	Manchester Amat. Photo. Soc.	"Making and Adjusting of Light Boxes for Orthochromatic Photography." Mr. Francis Fielding.
6.....	Newcastle-on-Tyne Photo. Assn.	"Rambles with a Gamekeeper." Mr. W. Percy Mail.
6.....	Jersey Photographic Society .....	Belgian Excursion.
6.....	Warrington Photo. Society .....	"Odd Traipses." Mr. A. H. Hughes.
6.....	Bristol Photographic Club .....	"Lantern Slides by Reduction and Contact." Mr. Fred Little.
6.....	Redhill and District Cam. Club ..	Social Evening. Exhibition of Pictures by Mr. T. Percival Padwick.
6.....	Brentford Photo. Society .....	Affiliation Competition Slides R.P.S. 1905 Set.
6.....	Otley & Dis. Cam. & Art Soc.	"Natural History Photography." Mr. R. Fortune, F.Z.S.
7.....	Hampstead Scientific Society ...	"Orthochromatic Photography." Mr. R. W. Wylie, M.A.
7.....	Redcar and Coatham Ph. Soc.	"Enlarged Negatives." Mr. J. W. Walte.
7.....	Photographic Club .....	"Bunyan."
7.....	Cricklewood Photo. Society.....	"The 'Richmond' Self Toning Paper." Mr. R. Morgan & Kidd.
7.....	Everton Camera Club.....	"Wheel Wanderings in History Places." Mr. W. S. Johnson.
7.....	Leeds Camera Club .....	"Genre Work." Illustrated. Mr. Henry W. Dick.
7.....	North Middlesex Photo. Soc. ..	Lantern Slide and Print Competitions.
7.....	G.E.R. Mechanics' Institution...	"Amateur Portraiture." Mr. H. W. Bennett, F.R.P.S.
7.....	Sunderland Camera Club .....	Amateur Photographer Prize Slides.
7.....	Edinburgh Photo. Society .....	"A Sketch History of Engraving." Illustrated. Mr. Geo. M. Alkman.
7.....	Coventry Photo. Club. ....	"Velox and its New Applications." Messrs. Griffin.
8.....	Hastings and St. Leonards P.S.	Photography Prize Slides.
8.....	Richmond Camera Club .....	"A Winter Holiday in Greece." Mr. A. Cheese.
8.....	Pudsey and District Photo. Soc.	Members' Competition. Making Lantern Slides.
8.....	London and Prov. Photo. Assn.	Open Night.
8.....	Hull Photographic Society .....	"Finland." Mr. E. Hewat Fraser, M.D.
8.....	Liverpool Amateur Ph. Assn....	"Architecture for Photographers." Mr. F. O. Cresswell.
8.....	Harrrogate Camera Club .....	Members' Night.
8.....	Rodley, Farsley, & Calverley Dis.	Members' Night.
8.....	Blenheim Club.....	Smoking Concert.
8.....	Rugby Photographic Society ..	Members' Night.

WALKLEY CONSERVATIVE CLUB, CAMERA, AND OPTICAL LANTERN SOCIETY.—"Crystals under the Microscope" was the subject of a lecture given last week by Mr. J. Wreaks.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING, Tuesday, February 27, the President, Major-General Waterhouse, in the chair. Mr. J. Page Croft gave a demonstration of his new ready-made gum-bichromate paper. He showed, by developing a number of prints, the very great opportunity for controlling the character of the result. Development was very rapid and could be accelerated as much as might be desired by the use of hot water. It was not advisable, however, to exceed a moderate temperature as the coating of colloid and pigment then became so thick that it was difficult to control its removal by hand. The chief danger of the process was over-exposure. The paper was at least five times the rapidity of P.O.P.—some people put it at six times—so that if too much exposure was given the development had to be forced and the range of tones which was otherwise obtained was lacking in the finished print. A number of questions were asked by members of the audience and answered by Mr. Croft.

Messrs. C. E. Kenneth Mees and S. E. Sheppard then gave their paper on "The Estimation of the Colour Sensitiveness of Plates." They reviewed the various methods of testing orthochromatic plates, including Abney's various forms of sensitometer, the Chapman plates plate-tester, and Eder's method of using three screens in front of a rotating sector wheel. They naturally laid great stress upon the spectral composition of the light used for testing, and gave the formulae for colour filters which would so adjust their actinylene that it gave a very close approximation to daylight. The method they adopt is to find the H. and D. inertia numbers beneath blue, green, and a red screen, so that some practical data can be arrived at; that is to say, they practically divide the spectrum by means of broad banded filters into three parts, and determine the H. and D. speed for each. Numerous tables and curves of various tests, thus measured, were shown, and incidentally the value of this method was proved by a series of results of bathing plates with acyanol in baths of different strengths, and for different times, and the authors prove that a 2 per cent. solution and three minutes' bathing, followed by ten minutes' washing, is the best. The conclusions drawn from the experiments by the authors is that the sensitising power of a dye is connected with its instability to light, and a sensitiser must have an absorption band in the region for which it sensitises, and that it must dye the silver bromide itself, and not merely the gelatine. Finally, a new method of spectro-sensitometry was outlined, in which a narrow band of the spectrum could be isolated and allowed to fall upon a plate wave-length by wave-length, plotting the results in energy units; or by using broad bands of light the integrating effects of broad-banded filters can be obtained. The difficulty lies in the amount of time required to ensure the plates, as one plate would require about 200 density measurements, and the plotting of from 15 to 30 separate curves. The authors, however, held out the hope that a new type of measuring instrument might remove this difficulty.

A brief discussion followed, in which Mr. Renwick and the chair took part.

NOVEL POSTCARD COMPETITION.—The Bristol Photographic Club arranged an original form of competition in connection with their exhibition next October. This is a daily competition for postal postcards during the run of the exhibition. The cards received each day will be judged separately and prizes given; they will then be immediately shown on a screen in the exhibition, and will prove a popular and interesting variation to the other bits. In addition to the "Open" classes already announced, there will be five "Members'" classes, and a General Subject class for residents within a 25 mile radius of Bristol. The latter is intended as an inducement for the local clubs and pictorial workers to take a special interest in the exhibition, and to bring them into contact with each other. The Hon. Exhibition Secretary is J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

WATFORD CAMERA CLUB.—The annual dinner of the Watford Camera Club was held on Monday, the 19th February, at the Malden Hotel, Watford, Lord Hyde, the president, in the chair. A presentation was made to Mr. E. H. Jackson, in the shape of an album of contributions by members, in recognition of his work as secretary.

EDINBURGH PHOTOGRAPHIC SOCIETY.—The fifth annual dinner of the society was held on February 22 at the Carlton Hotel, the president, J. Tudor Cundall, B.Sc., occupying the chair. The menu and toast list was produced by J. F. Buttrick, vice-president, the items being printed on the plain side of a stout bromide paper, which bore on the reverse, photographic impressions of Edinburgh and the Society's emblem. The toast of the Edinburgh Photographic Society was proposed by J. Craig Annan, and was responded to by D. W. Thompson.

BLAIRGOWRIE AND DISTRICT PHOTOGRAPHIC ASSOCIATION.—The annual meeting held last Tuesday in the Photographic Rooms, Blairgowrie, was presided over by Vice-President Deuchars. The secretary showed an increased membership, and the treasurer a depleted exchequer owing to loss sustained in connection with the last exhibition. Office-bearers were elected at follows:—President, Alex. Geekie; vice-presidents, James Deuchars and James Richardson; secretary, Lake Falconer, junior, James Street Cottage, Blairgowrie; treasurer, D. S. MacLennan. On Thursday the association held its annual "At Home" in the Public Hall, when about eighty were present. The dull sameness of the walls was relieved by pictures from the association's permanent collection, as well as several from private members. The wee tables, decorated with dainty spring flowers, made an enticing picture. Provost Smith welcomed the visitors on behalf of the association, and ex-Bailie Spalding proposed thanks to the ladies committee who had so excellently attended to the purveying. During one dance the lights were lowered, and the coloured limelight playing over the dancers provided pleasing effects. Ogilvie's orchestra was in great form. J. D. Petrie was an energetic M.C., and the whole function went with pleasurable vim from start to finish.

SOUTHSEA PHOTOGRAPHIC SOCIETY.—The Southsea Photographic Society held their eighteenth annual general meeting in their premises, 5, Pembroke Road, Portsmouth, on February 21. The honorary secretary congratulated the members on the great success of the exhibitions held by the linked societies of Hove, Southampton, and Southsea, the support accorded them justifying their being adopted as permanent fixtures. The financial statement showed a substantial balance in hand. A unanimous vote of thanks (following the presentation of a handsome camera) was given to the retiring secretary, Mr. J. J. Lawton, for his invaluable services during the past two years.

BRISTOL PHOTOGRAPHIC CLUB.—On Tuesday in last week, Mr. Percy G. R. Wright gave a lantern lecture, entitled "A Square Mile in Holland." The "square mile" was in and about the little fishing village of Volendam, situated on the Zuyder Zee, and the high pictorial quality of the slides shown furnished a good object lesson of what large possibilities there are in a limited area to a photographer with a "seeing eye." While the lecturer's humorous discourse provoked much laughter, his pictures gave a very real insight into the quaint customs and surroundings of these Dutch fishing folk. Mr. Wright's method of dealing with the overpowering attentions of the Dutch children is worth noting. It was to single out the ringleader, rush up to him, effusively shake his hand, and continue to do so while dragging him along the road, talking volubly in English, until the boy in dismay turned tail and ran, followed by his companions. Also, it is well to know that there is only one inn in Volendam. It is practically monopolized by artists, so that it is best to get an introduction before applying for accommodation there.

EDMONTON AND DISTRICT PHOTOGRAPHIC SOCIETY.—On Wednesday, February 31, Mr. Ernest Human gave a practical demonstration of carbon printing. After explaining the theory of the process, he described the sensitising of the tissue, and recommended the following bath:—Potash bichromate,  $\frac{1}{2}$  oz.; water, 19 ozs. Dissolve and add two or three drops per ounce of liq. ammonia, .880, the tissue to be immersed in the bath from thirty to fifty seconds, taking care that no air bells formed upon it. He explained the safe edge and its use, saying that he preferred to use paper masks rather than the opaque colour on each negative, as by their use much saving of time could be effected. He passed round five different print meters used for the process, but said that perhaps the better plan for beginners was to choose another negative of about the same density, and print side by side with a sheet of ordinary P.O.P., which, when printed to

finished, *not to toning*, depth would give the correct exposure for the tissue.

**OXFORD CAMERA CLUB.**—At the close of the annual meeting a lecture was given by Miss Poulton, illustrated by a remarkable series of photographs taken by Mrs. Poulton. The particular marriage described appeared to have particular interest in as far as the bride had been chosen from among the other brides of the chief to be the queen of the people. The photographs showed the gathering of the bride's party and of the friends of the bridegroom. These took up positions some distance apart, and between them sat the bridegroom alone. Then followed a series of war dances, after which the bride appeared with presents. The public interrogator questioned the bride on her feeling towards the bridegroom, thereby obtaining indirectly marriage vows. At the conclusion of the ceremony, the bride ran away suddenly, and the bridegroom had to pursue and capture her before claiming her as his wife. The ceremony lasted on the occasion in question a whole day.

**CROYDON CAMERA CLUB.**—Mr. H. W. Bennett, on the 21st ult., gave a most interesting and instructive lecture on "Architecture and the Camera." Nothing, in his opinion, could be fitter subjects for the camera than old stone and wood work, but their form and character should be preserved faithfully, and with no attempt to get away from texture, under the pretence of furnishing a so-called pictorial rendering. The latter would be secured by a proper selection of time and circumstance. The churches were practically open to everyone, but all should remember that they were allowed to photograph in sacred edifices, not as a right, but as a favour. The lecturer then passed on to a clear description of the various styles of architecture, from the Conquest to the Reformation. Architecture was then a living art, progressing and developing. A very large proportion of the buildings remained, and would probably be still in existence a thousand years hence. The Reformation marked the beginning of the decline, the decorative style existing then producing ornaments merely for ornament's sake. The photographer should study the various styles, and the modifications necessarily imposed by local materials and conditions, and endeavour to give prominence to the salient features of each style. Turning to practical points of procedure, Mr. Bennett said, in dealing with near objects, a great deal might be done by changing the height of the camera. If it were placed too high, the floor had frequently a curious up-hill appearance. The generality of subjects were best taken with the plate vertical, which gave an impression of height oftentimes wished to be conveyed. Further emphasis in this direction could be secured in the print by trimming it long and narrow. Never, said the speaker, show an arch or column, *almost*, but not *quite* complete; depict them broken away early, the "almost complete" being invariably bad. He also uttered a word of caution against the absence of foregrounds, a very common fault in architectural photographs. As to apparatus, whatever form was chosen, rigidity must be regarded as essential, and the tripod should be capable of an up and down movement, without altering the adjustments of the camera. Personally, he employed fast, but not ultra-rapid brands of plates. The anastigmat lenses were far and away the best for the work, for a 1-1 plate he generally used three, about 11, 8, and 6 inches focal length. If only one lens was available, then this should be a little shorter than the length of the plate. The detached triangular levels, for application to the focussing screen, or the side of the camera, were convenient, as was a focussing magnifier for examining the image. In the subsequent discussion, Mr. Bennett said he did not place reliance on meters. As an illustration, the exposure for the same shadow—in which the meter might be placed—could very easily vary in the proportions of 4 to 1, or even more, according to the point of view. An apparently guileless question by Mr. Sellors, as to whether Mr. Bennett advocated mechanical or factorial time development systems, drew the lecturer immediately in strong opposition thereto. With the names of Messrs. Hurter and Driffield, flying through the air, and graphic curves falling thickly on the blackboard, a battle royal appeared imminent. The hour was, however, late, and the vice-chairman, Mr. Terry, pleasantly applied the closure by proposing a hearty vote of thanks to Mr. Bennett, which was carried in the usual way. Before leaving, Mr. Bennett kindly expressed his willingness to devote an evening to a discussion on that much-vexed question, "Control in Development." It is anticipated that the evening will be a lively one.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### WANTED: A BOOK ON STUDIO LIGHTING.

To the Editors.

Gentlemen,—In pursuance of my contribution to your valuable paper dated 9th December, 1904, I felt highly flattered to meet, on my return to England, quite a number of the photographic fraternity, who carefully preserved their copies of that date, and who racked their muddled intellects to find the solution of my theory, and were so eager to put it into practice.

And I confess that my fear was changed to disappointment at not receiving the expected R.S.V.P. from one or other of the more enlightened members of the profession.

In the days of my photographic beginnings, and which does not date far back, I was under the false impression that, except for a smattering on a ruddy hill in Surrey, all the knowledge of studio lighting had gone adrift, and was eventually centred in a little spot Transatlantic; and where your esteemed contemporary took an active part in publishing a pretty picture pamphlet in which I was foolish enough to invest half a dollar.

Surely it is a lamentable state of things not to find a practical treatise on the subject. Yea! more lamentable, indeed, to find so many incapable of grasping it.—Yours truly, ANGLO-INDIAN.

Birmingham, February 26, 1906.

### COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—In your issue of last week Mr. Edw. T. Butler challenges a statement of mine. Please allow me a few words on the same subject.

It is said that Ducos du Hauron invented a reflector system for colour photography. I could not find any information on this point in the Patent Office Library, which contains about 40 volumes on this subject, nor in the patent records of England and France kept at the same place.

The first English patent I have to quote is that of Ives, 4,606, 1892; then again, Ives, 2,305 and 3,784, both in 1895. The first one of these patents is the camera, of which the illustration is now shown in all the text-books; the second one is a three-step arrangement, which also allows a two-step variety, and is known as the chromoscope. The payments of these patents have not been kept up. Why? Because no negatives of equal size could be produced for printing purposes, and when the boom for chromoscope had passed away the thing was of no further commercial value. Nevertheless Edwards 3,613, 1895, tried to file a patent with two-step arrangement, which was contested and lost; then White, 8,663, 1896, turned the camera upside down, also not showing any steps.

The Edwards form, by changing the place for colour screens was resuscitated in 29,353, 1897. But Bénéto, with 28,920, 1897, took a perfectly new line with only one screen, which latter patent Butler, 9,936, 1900, adapted for stereoscope. Ives' first idea is rejuvenated with patent 10,993, 1902, having an addition of faced mirrors. In this year's "Almanac," Mr. Butler's third attempt in three-colour one-exposure cameras, Patent No. 4,209, 1905, is given, which patent differs from his first in that the screens are placed nearer the slides, and in the same "Almanac" an illustration is shown from Hans Schmidt, giving in a few lines the apparent action of light rays on two mirrors, which latter are supposed to act also as colour filters.

I may take Schmidt's interpretation—being despoiled of all invented shells—as being the solution of all the above-named patents, and I maintain that not one of them will give three pictures of the same size.

I believe that Ives has abandoned the here-quoted ideas long ago, because he tries to solve the problem by other means.

If in the above patents an angle of view of 5 to 10 degrees only is used, and also optical glass of not more than 0.5 mm. is employed for the mirrors, then approximately correct size is possible, but if

ass of 2 mm. thickness is used for the reflectors, and if an angle of view of not less than 25 degrees is permitted, that is, if practical requirements for daily use and not delicate playthings are aimed at, then permit me to repeat, not one of the above now known reflector systems will give negatives for accurate superposition for printing methods. Mr. Butler does not ask me to give him the optical solution on which I base my contention; he maintains that prints are sufficient proof. May I go one step further and say negatives sufficient for the present, and even not smaller than half-plate

herewith send our respected Editor a half-plate set of negatives verification. The negatives will show unmistakable proof that they were taken with one-exposure, and they are all the same size as are taken with a system (to my knowledge) not yet known. Will Mr. Butler, or any one else, willing to contest my assertion, bring forward similar proofs, in a word, by independent judgment firm or contradict my statement on the above-named patents.—Yours respectfully,  
OTTO PFENNINGER.  
105, Hythe Road, Brighton, February 26, 1906.  
It seems to us that our correspondent adduces proof of a kind which he is not willing to admit from others. The negatives, however, which he sends, are excellent in respect of equality of size. —B.J.P.]

# THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION IN PARIS.

To the Editors.

Gentlemen,—You have published in your issue of the 9th February note on the second Exhibition of Photography of Paris, 1906, the article of which compels me to send you the following reply, which I rely on your sense of justice, your devotion to the British interests, your solicitude for your readers to insert in your next issue. From the reading of the paragraph in your No. 2,388, it may be inferred that the forthcoming Exhibition has a close connection with the now in progress in one small room in the Grand Palais des Champs Elysees. This is absolutely without foundation. You further suggest that the help and patronage of the Photo-Club Société Française de Photographie are essential to the success of the proposed Exhibition, and have still to be obtained. I shall be glad if you will allow the organisers of the Exhibition to point out that they do not intend to apply for this patronage. I do so would be to relinquish into the hands of the above-named societies much of the control of the Exhibition, and as organisers hold the strong opinion that the success of the Exhibition rests entirely on its absolute independence and its international character it is obvious that there has been no intention of seeking official support.

view of the publicity which has been accorded to this mistaken view of affairs, the organisers hope that you will enable your readers to understand their actual intentions.

The thirteen groups composing the Exhibition only one deals with the amateur aspect of photography, with which the Societies concerned are concerned, and their good will, or their ill will, is material to the success of the Exhibition.

The best reply that can be offered to the suggestion that the Exhibition is unsupported is to give the names of some of its distinguished supporters: The Ministries of Commerce and Industry, the Works, the State Departments of Post and Telegraphs, Fine Arts and such eminent men as the Presidents of the General Council of the Seine and the Municipal Council of Paris. Mm. Becquerel, Delat, Lippmann, Loewy, Edmund Perrier, Emile Roux, etc., etc. will also be exhibitors from the national Printers, the Observatory, the Museum, the Trocadéro. Collections of Historical monuments and the National-Conservatoire of Arts and Crafts, the d'Histoire Naturelle, etc.—Yours faithfully,

L. GASTINE, Le Commissaire Général.

Place de Vaugirard, Paris, February 25, 1906.

was not our intention to suggest that there is any connection between the proposed exhibition and that recently held, nor do we the paragraph bears this interpretation. It was precisely with a motive to which our correspondent refers that we alluded to matter, and to the fact that the official bodies representing French artists and the photographic trade have expressed their intention to participate in the Exhibition.—Eds., B.J.P.]

## SENSITOMETRIC TESTS.

To the Editors.

Gentlemen,—Allow me to offer my sincere thanks for the delightful articles on sensitometry by Mr. Mees. Two things occur to me through reading them.

How is one to obtain the constants of the various plates on the market?—the only place I have ever seen them in is the B.J.P.

The other point is to ask if it would be possible for Mr. Mees to give us some information as to how to obtain a constant development factor under varying temperatures?

The method of Mr. Watkins is the only one I know of which attempts to do this, but I fancy it is liable to wide error.

Could Mr. Mees not discuss this for us?—Yours faithfully, Q. S.

Mr. Mees writes:—"In reply to your correspondent, 'Q. S.,' the articles on sensitometry were written to explain the constants given in the B.J. I think that readers might possibly find these for themselves, but I couldn't advise them to try. As regards the effects of temperature, this has been discussed by Ferguson and Howard (PHOT. JOURNAL, March, 1905, and B.J., March 31, 1905). The effect of altering temperature is simply to alter the value of K. (The theory of Phot. Processes, Part II., Phot. Journal, October, 1905). This same paper contains a preliminary discussion on Mr. Watkins' theory. The Watkins method may, under some circumstances, produce wide errors, but I should have said that usually, with care, it would compensate for variations of temperature in a quite satisfactory manner."

## Commercial & Legal Intelligence.

**BANKRUPTCY** at Smethwick.—At West Bromwich County-court, last week, Charles Frederick Morris, of Cheshire Road, Smethwick, and carrying on business in Dudley Road, Birmingham, as a photographer, came up for his public examination. The meeting of the creditors was reported in our issue of February 16. The bankrupt said he was engaged as a photographer's assistant until 1887, when he commenced business on his own account in Dudley Road, Birmingham, with a capital of £5, which he had saved. In 1900 he opened a branch shop at High Street, Smethwick. He subsequently purchased the property for £350 with money advanced by his bankers, who were secured by the deeds of the property and two policies. He traded without difficulty until December, 1903, when he was in arrear with his rent, and his landlord lent him £50. A few months later he borrowed £20 from a professional moneylender, and agreed to repay £25. During the last two or three years his receipts had not been sufficient to pay his expenses. In June, 1905, the Smethwick property and the two life policies were sold by his banker, who received £494. Witness admitted that his wife signed some of the bills as surety to money societies, but in five out of six transactions the bills were signed by one of his servants, who at the time was in receipt of wages amounting to £2 5s. a week. These bills were for £50 each. The debtor was allowed to pass.

THE application of Miss Florence Smithson, of the Lyric Theatre, for an injunction against the Rotary Photographic Company, Ltd., and Mr. Chandler, a photographer, of Exeter, to restrain them from publishing certain of her photographs has been adjourned. The case will come before the High Court about the time of publication of this issue of the B.J.

**NATIONAL Photographic Printing Co., Ltd.** (Manchester).—Issue on January 8 of £800 Five per Cent. Debentures, being the whole of a series created same date, charged on the company's undertakings and property, including uncalled capital. Holders: Palatine Pictorial Company, Ltd., 281, Deansgate, Manchester. No trustees.

**COMPANIES Registered.**—Wilfred Emery, Ltd. (87,641). Registered February 17. Capital, £2,000 in £1 shares. Object: to acquire and take over as a going concern the business of photographers, developers, and enlargers of photographs, photographic printers, manufacturers of and dealers in cameras, lenses, papers, cards, and photographic materials, etc., carried on at 89, Cricklewood Broadway, as Wilfred Emery. No initial public issue. Registered without articles of association. Registered office: 89 Cricklewood Broadway, Cricklewood.

## Answers to Correspondents.

- \*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*.\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \*.\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- F. Proctor, 27, Bark Street, Bolton. *Photograph of Mr. A. H. Gill, M.P. for Bolton.*
- Mrs. M. McBride, 29, Market Square, Lisburn, County Antrim. *Photograph of the Revs. J. McGroth, J. Meealey, J. Fuller, and M. McCashin.*
- V. C. Baird, Gowanbrae, Broughtly Ferry, Forfarshire. *Photograph of Victoria Galleries Dundee.*

SILVER STAINS.—Please say in your next issue whether you know of any means of removing silver stains off negatives that have got wet.—F. C.

Soak the negative in potass iodide, 200 grains; water, 10 grains, and after washing transfer to potass cyanide, 300 grains; water, 10 ozs., in which rub the stained part with a pledget of cotton wool. If the stain does not yield to this treatment a solution of iodine (in potass iodide) may be used in place of the first solution, but with caution.

COPYRIGHT.—Sometime ago a professional friend of mine had his photograph taken by photographers in Belfast, and paid for same in the ordinary way. After some weeks duration he was surprised to find that — had put the same on the market in post-card form. He immediately wrote to the firm of photographers complaining of this, and told them to stop the sale, as he had not given his permission for their publication, but up to the present he has received no satisfaction whatever. Now, what I want to know is, Do you consider this a case under the copyright law? I should like to make it plain to you although my friend is a professional man, he went into the studio as any ordinary individual would, not at the photographer's invitation.—SILENCE.

If your friend paid for the sitting in the usual way the copyright is certainly his, and neither the photographer nor the — have any right to use it. You will find the conditions under which he can proceed against the parties explained in the article on "Copyright" in the "Almanac."

PRINTER.—We have no authentic information beyond the fact that wages are from two to three times those in England, and living correspondingly expensive.

F. D.—We can only suggest that you ask the people for a prospectus of the proposed exhibition.

H. BRADSHAW.—1. We hardly think that you will be able to obtain a purple tone with the bath you name. You had better try that given just above it in the same article. 2. As regards the thiocarbamide bath you should dilute the bath still more, as it works too quickly to give you the warm purple. 3. No, carbonate of soda is not the bicarbonate; use carbonate of soda pure crystal.

A. G. NEWARK.—There are two principal causes for the mottled appearance of your prints. The first is damp in the printing

frames, and secondly, too cold a developer. We presume you are using rubber pads in your frame. See to this, and raise the temperature of your developer to at least 65 deg. Fahr.

MISS MAY BROOKS (Leeds).—We have made enquiries, but cannot discover the present address.

GLAZING P.O.P.—Can you give me a method of obtaining a gloss P.O.P. postcards, beyond the tedious way of squeegeeing or plate-glass?—NO-IT.

We know of none. If the squeegeeing method is carried out on a large scale, and in a well-warmed room, it need not be tedious.

BLACK-LINE COPIES.—The enclosed print is from a tracing with black lines. Can you let me know by what process it is done. If so, please give formula for same.—W. H. S.

The print is made by a process which is on the market in several forms, and is probably somewhat as follows:—Smooth sized paper is coated with:—Gum arabic, 110 grains; potass bichromate, 30 grains; alcohol, 5 minims; water, 1 ounce. It is exposed and washed in water until the lines look engraved. It is then coated with shellac and lamp-black (applied with a sponge), and when dry placed in sulphuric acid, wherein the superfluous black is removed. You will find these methods described in "Ferric and Heliographic Processes," published by Dawbarn and Ward, price 2s.

DRY MOUNTING.—I have made the formula for dry mounting (of M. Briand's) given in "Almanac," page 846, and cannot get it to stick with once coating. If I coat the tissue paper both sides twice it sticks well. Can you suggest any alteration in the formula to give more body, so as to save the second coating, I use the best bleached tissue. If you cannot suggest any alteration, could you give me M. Briand's address, or the address of the "Photo Gazette"?—RUSTICUS.

Possibly all the shellac has not been got into solution. About 800 ccs. spirit should be used to dissolve it, and the remainder employed for the elemi and balsam. You will find the address of the "Photo Gazette" on page 872.

E. J. P.—The results will be made known in a few weeks.

G. J. II.—In our next.

J. C. B.—We are unable to offer any explanation. We would suggest that the maker's formula for the developer be used.

J. P. S.—T. S. Bruce, 4, Villas on Heath, Vale, Hampstead, N.W.

T. V. BIGGINS—See the list published from time to time in our pages—last on January 12.

IMPROPER Postcards.—The police-court reports each week for some time past have added to the list of convictions of tradesmen selling picture postcards of an objectionable kind. At Hastings last week the magistrates sentenced a tradesman to three months' hard labour, without the option of a fine, for exposing objectionable postcards for sale. An order was made for the destruction of several hundred cards. At Marlborough-street three shopkeepers in the neighbourhood of Leicester Square were heavily fined for displaying picture postcards of the same character in their shops. In two cases the fine was £25, and in the third £5.

\*.\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

An exhibition of work by the Pulligny-Puyo "anachromatic" is opened at the Photo-Club in Paris on Thursday in last week. A review by M. Robert Demachy appears on page 184. Some notes on the optics and advantages of the lenses in portraiture are contributed by MM. Puyo and de Pulligny. (P. 184.)

Gastine, the Commissionnaire-Générale of the forthcoming International Photographic Exhibition in Paris, informs us that the abstention of the various "chambres syndicales" is not preventing individual firms from granting the exhibition their support. (P. 197.)

our Photography.—Mr. Howard Farmer suggests that the exhibition of examples of colour photography, which remains open at offices until March 17, should be established in some suitable as a permanent collection. (P. 198.)

our Photography.—The latest account of the forthcoming starch-grain process has been published. MM. Lumière also patented a one-lens one-exposure camera. (P. 190.)

Simmance-Abady photometer of the flicker type has been applicable to density measurements. A record of some experiments explains the method of using and comments on the readiness with which accurate readings can be taken. (P. 183.)

patent has been taken out for casein as the vehicle of pigment bichromate in a printing process. (P. 193.)

the rather unexpected properties of silver sulphide are described their bearing on the permanence of sulphide-toned bromide discussed. (P. 180.)

## EX CATHEDRA.

### Artistic Lenses.

The space devoted in this issue to a unique exhibition which opened in Paris at the end of last week should be deemed well filled by all concerned with photographic portraiture. The fact that a certain degree of softness is obtainable without destruction of textures is no new discovery, though the advantages of a certain amount and a certain kind of aberration in a lens for portraiture has not received a fair share of attention. It is significant of greater interest in the matter that simultaneously with the opening of the "anachromatic" exhibition in Paris last week, Messrs. Dallmeyer should have come out with a convenient method of producing diffusion by the old expedient of displacing the back cell of the portrait lens. MM. Puyo and de Pulligny claim for their partially corrected lenses facilities in soft definition, long focus, and small cost. They do not put them forward as substitutes for anastigmats in critically covering a wide angle or for portrait lenses in giving the very finest definition at a very large aperture.

\* \* \*

### Reducing Sulphide-toned Prints.

In a previous note (February 16) on sulphide-toning we suggested two possible explanations of the action of reducing solutions, such as "Sanzol," on the brown toned image. The first was that as silver sulphide is readily chlorised, the solutions might act directly on the sulphide in the image. The second was that the sulphiding action might be incomplete, and residual silver salts soluble in the reducing solution might exist in the image. We have now tested both suggestions. The second proves to be possible but unlikely, for while silver salts undoubtedly exist in very slightly toned images, none can be found if the ordinary sodium sulphide bath is applied for ten minutes or so. Boiling in a thiosulphate solution failed to remove any silver from a number of prints that had been passed through the sulphiding process under quite ordinary conditions. In testing the other suggestion, however, we arrived at what may appear to be surprising results, considering the reputation that silver sulphide has achieved for stability. We prepared some black monosulphide by precipitation from silver nitrate with ammonium sulphide, and found that this compound is affected by various solutions in precisely the same way as brown toned prints. It is chlorised by potassium bichromate and hydrochloric acid; very readily iodised by a solution of iodine in potassium iodide; and very rapidly attacked by bromine water. It is slowly affected by a solution of potassium ferricyanide and potassium bromide, while Farmer's reducer, ammonium persulphate, and chromic acid all dissolve out silver from the black sulphide. It

therefore, appears that the facts that the toned bromide image is affected by reducing solutions, and that the toning process can be repeated over and over again, do not in any way disprove the existence of silver monosulphide in the brown toned image. On the other hand, it seems that the stability of silver sulphide has been somewhat exaggerated. It is proof against sulphuretted hydrogen, which is the chief enemy of the silver print, but if the halogens are also looked upon as potential enemies, there is little to choose between the sulphide and the metal.

\* \* \*

#### **Washing Sulphide-toned Prints.**

In the course of experiments made on the action of reducers, we had occasion to soak some toned prints in acid solutions. As a result, all these prints that had been treated with the potassium ferricyanide and potassium bromide bleaching solution showed blue stains, which clearly indicated the presence of ferri- (or ferro-) cyanide compounds in the paper. None of these prints had been washed for less than half an hour, but it is evident that the operation was very incomplete, and that much longer washing is desirable. We are inclined to think that as a rule the washing is very much underdone. Published instructions often suggest that little more than mere rinsing is required, but from our experience it would appear that as much washing is required after toning as after fixing. Ferrocyanides left in the paper must decompose sooner or later, and blue stains will inevitably be the result.

\* \* \*

#### **Caseine In Photography.**

As will be seen from our "Patent News" column the specification of a patent has been published for a pigment printing process without transfer. The vehicle holding the pigment is an emulsion of caseine, soap, and gum arabic. Caseine is really no new substance in connection with bichromate photography. In 1870 the late Mr. J. R. Johnson obtained a patent, in the carbon process, in which caseine was to be used in the tissue, wholly or in part, in place of gelatine. As it may be of interest to some of our readers who may not know how to prepare caseine for photographic purposes, we here quote from the official abridgment of Johnson's specification, No. 201, 1870: "Third improvement—Replacing the gelatine, in the above compounds, wholly or in part by curd or caseine, etc., which is insoluble in warm water, but which is rendered soluble by ammonia or other alkali. The caseine is precipitated, with rennet, or by an acid, from skimmed milk. The resulting curd is collected on a filter, dried by pressure, and dissolved in dilute ammonia. This solution is used instead of a portion of the gelatine solution." In the same, and following, year patents were obtained by Baldock, Denne, and Hentschell for producing printing surfaces with caseine, soap, and bichromate of potash. In the recent patent it is mentioned that the ingredients do not combine so intimately as they do with gelatine, and the print has not the same homogeneous surface, but appears granular and irregular. The working of the process generally seems to be similar to that of the ordinary gum-bichromate process.

\* \* \*

#### **Human Electricity.**

According to one of the German lay papers, Herr Einthoven has invented an extremely sensitive galvanometer, by means of which he has measured the electricity of the body. The instrument, which will measure the millionth of an ampere, consists of

a silvered quartz fibre stretched between the poles of a strong electro-magnet. When the faintest current passes through this fibre it moves in the direction of the lines of the magnetic field, and the movement can be directly measured by means of a microscope, or it can be recorded by means of photography. The new instrument may be used to study the current of electricity that flows through the human nerves. The action of the human heart has already been measured by Lippmann's electro-capillary instrument. It is well known that the muscular contractions in the beating of the heart produce variations in the electric resistance of this organ; this was determined by Waller in 1898. Einthoven claims now to have detected, by the aid of photography, electric waves, which correspond to the beating of the heart, and proved that the electric phenomena alter with every beat. The waves are similar in form to those of the cardiograph invented by the late Professor Marey. Possibly in the future we shall be able to record by the aid of photography the state of a person's health, or the phases of neurotism and hysteria, or Mr. Mees may be able to plot the wailing and fretfulness of a peevish child.

\* \* \*

#### **Measuring Shutter Speeds.**

A writer to a contemporary revives in modified form the method of timing a shutter in which the object moving at an alleged known speed is a pendulum swinging under the influence of gravity. The method is as follows:—A heavy pendulum is suspended a few inches from its upper end, to which is attached a small platform on which a camera is mounted. The platform is adjustable so that the lens of the camera can be pointed to the sun—which must be shining at the time the measurement is made. The pendulum is to be of length to swing seconds, and it is set swinging over such an arc that the image of the sun falls on the focussing screen at each end of the swing, and at this amplitude of swing an exposure is given during one complete swing. Result, a line on the plate representing the movement of the sun's image in one second. The next step is to make another exposure for a time provided by the shutter to be tested. The writer directs that the pendulum should be started from the same point as in the previous exposure to ensure equal angular motion, and suggests that the result obtained—a short rod representing the time the shutter remained open—correctly expresses the ratio of this time to the one second obtained by the first exposure.

Even with certain precautions which the writer mentions it seems to us that it can rarely do so. The writer appears to ignore the law of the velocity of the pendulum, viz., that the velocity is zero at each end of the swing and a maximum at the mid position. Hence the length of a short sun line will vary with the position of the pendulum when the exposure was made, and for this reason, in the first place, the method cannot be accurate. In addition, the friction which must enter into the case, considering the very primitive method of suspending the pendulum, will disturb the velocity irregularly, and further, a certain amount of work is done in bending the flexible tube, and will make the velocity again more variable. It may be that one of these indeterminate errors will partly neutralise another, but that fact can hardly excuse a method which is claimed to be more accurate than the revolving wheel method, which the writer describes as "little better than useless." However, we will spare the letter further criticism since the writer appears to have some haunting fear that all is not right, else why the last paragraph:—"The exposure of the shutter should not be made at just the end of the swing of the pendulum, or when the bob is at the lowest point of the arc of movement. At these two places there

ther a slight acceleration or retardation of the angular movement. To ensure accuracy the snapping of the shutter should take place at another part of the swing." We ask the writer: What part?

\* \* \*

**Reading in Photography.** Frequently has it been found necessary for us to comment upon the way that some modern writers refer to, or describe, the processes that were in use in the earlier days of the art. This they have done innocently enough, through ignorance of what the processes really were. To give two examples of this we may mention that the cyanotype process and the wax paper process are often counted as being one and the same, inasmuch as in each the negative has been waxed. The Sel d'or toning process is sometimes applied to the old combined toning and fixing process, while the difference between them is just as great as the modern separate toning and fixing methods, and the combined bath. Seeing these misconceptions now, it is difficult to imagine that similar ones will obtain in the future with regard to the processes of the present day, and that with perhaps quite a good reason. By way of example, the three now most popular printing processes: P.O.P (printing out paper), albumen, and collodio-chloride. These are popularly known as "P.O.P.," "silver," and "chloride," and are so noted in advertisements of printers requiring situations, and photographers requiring assistants. Similarly terms were used in the catalogues of the Royal Photographic Society's Exhibitions, when the processes by which the pictures were made were mentioned. As all three processes are essentially the same, and as the essential difference between them is the vehicle in which the sensitive salts are held, would it not be better to distinguish them by simply calling them gelatine, albumen, and collodion?

### THE FLICKER PHOTOMETER.

Some time ago we had, through the kindness of a friend, the opportunity of trying a Simmance and Abady flicker photometer for the purpose of measuring densities, and as the flicker photometer is not often employed for such work, an account of our experiences may be interesting. The apparatus is generally arranged for the special work of measuring illuminants, hence it had to be modified slightly. A logarithmic scale of the Hurter and Driffield was used, and perforated screens were erected at the ends of the shortened bench, with single filament Nernst lamps behind the apertures. The general arrangement was nearly as possible that of the H. and D. photometer, the flicker photometer head taking the place of the spot chamber. As some readers are probably acquainted with the arrangement of the flicker apparatus we will be as well to describe it in detail.

One essential feature is a vertical revolving plaster of Paris disc with an alternately bevelled edge. The plane of the disc is at right angles to the bench, and the observer looks down on to its top edge, which is seen through a vertical tube fitted with a reflector. With the disc in position the right hand bevel alone is seen, and this is illuminated by the right hand source of light. As the disc makes half a revolution the right hand bevel

is at the bottom, and the observer sees only the left hand bevel, which is illuminated by the left hand source of light. If the right and left sources of light are unequal then one bevel is more brightly illuminated than the other, and the continuous revolution of the disc shows a more or less violent flicker. If, however, both bevels are equally illuminated, no flicker is observed. In use the disc is set rotating and moved right or left until all sign of flicker disappears. The correct adjustment is easily determined, and, though we were quite unfamiliar with the apparatus and not at all practised in photometric work generally, within a very short time from the start we were taking observations as readily and as accurately as the owner of the apparatus, who worked with us throughout.

This ease in taking observations is largely due to the fact that the sensitiveness of the apparatus is adjustable. The speed of the disc is regulated by a brake, and the violence of the flicker can be increased by lowering the speed. Therefore, when dealing with great densities that transmit very little light the speed of the disc is reduced to its lowest rate, and the flicker so rendered more obvious. Such high densities are then nearly as easy to read as the lower densities that transmit plenty of light. With the latter a low speed of revolution gives a painfully and quite unnecessarily violent flicker, therefore the speed of the disc is increased until there is just sufficient flicker for the purpose. It is, of course, obvious that persistence of vision will cause the flicker to disappear altogether if the speed is much too great for the intensity of the light. One of the advantages claimed for this apparatus is the fact that lights of different colours can be compared with the same ease as lights of the same colour. When the flicker is observed the two colours are, of course, given, but when the neutral point is reached and the flicker disappears, one sees simply a monochrome patch representing a mixture of the two colours. For some reason that is not very apparent it is not quite so easy to make an exact adjustment with differently coloured lights (there seems to be a certain amount of latitude of adjustment), but the error is not great, and the advantages of the flicker apparatus in the comparison of coloured lights are very great, though, perhaps, this is not a matter of much moment in photographic photometry.

As the apparatus has not been specially designed for density measuring it is naturally not so well adapted to such work as it might be. The disc and the driving clock are contained in the same chamber, hence this is somewhat bulky. In fact it is too bulky to permit the disc to be brought so close to a high density as is sometimes necessary. Supplementary densities on the other side can, of course, be employed, but if not prepared with sufficiently high ones the observations may be prematurely stopped. This occurred in our experiments, and we were compelled to abandon the measurement of two very high densities. This defect could, of course, be easily remedied. The disc could be contained in a very narrow chamber, while the clock occupied a larger receptacle underneath. The disc could then be brought close up to a density while the clock passed under it, or, better still, the clock could be fitted on the opposite side of the disc to the density. The clock might also be arranged to run for a longer time, and be fitted with a brake capable of more delicate adjustment.

These are, however, minor details in no way affecting the principle of the photometer, which struck us as being excellent and most readily adaptable to the purpose of density measuring. Incidentally we may mention that the Nernst

lamps proved very successful. The zero point was repeatedly determined in the course of about four hours work, and no fluctuations of any possible consequence were detected.

## ARTISTIC LENSES.

### THE EXHIBITION AT THE PHOTO-CLUB DE PARIS.

AN exhibition of photographs is now being held in the Paris Photo-Club Rooms. It is not an exhibition of pictorial works, yet it will prove more valuable to pictorial photographers than any salon.

Some years back M. L. de Pulligny and Major C. Puyo, both members of the Photo-Club, began to study, with improvements in view, the deficiency of pictorial rendering of the average sort of lens used by the average pictorial worker, and they soon came to the conclusion that ninety per cent. of the instruments on the market were over-corrected for this special purpose, and nearly all the rest under-corrected. In other words, the sharp pictorial work is generally too sharp and the soft pictures too fuzzy; there is excess of detail in the former, loss of drawing in the latter.

The Photo-Club exhibition of prints taken with anachromatic lenses has been organised with the hope of demonstrating *de visio* the particularly pleasing quality of the pictures produced by such optical combinations. The exhibition was open to all the different makers of this kind of instrument, but outside the Pulligny and Puyo lenses we only notice the single lens of M. Rolato Petion. The pictures sent in passed before a jury, who examined them from a purely technical point of view rejecting those that showed sufficient errors in development or lighting of the subject to neutralise the distinctive qualities of the optical combinations used in their production. Pictorial composition was not taken into account, and on my special request gum bichromate prints were excluded from the show, for an expert in gum can use a negative taken with an anastigmatic lens stopped down to *f*/60, and get an exasperated Bergheim fuzziness out of the resulting print simply by sugaring his sensitive mixture or grossly underexposing his print; in fact, we wanted pictures on a medium that did not run at will. Still, an important proportion of exhibits are printed on Fresson Artistique paper, ready made, and that goes under the name of gum-bichromate. I have no wish to risk an action for libel, so I will not say that there is no gum at all in the Fresson coating; but I can, at any rate, vouch from personal experience that the film acts as if there was mighty little and a great deal of something else. The outlines of the figures are always perfectly clear and sharp, and there is no softening effect due to overlapping of more or less soluble zones. This seems to point towards gelatine.

So Fresson paper was admitted, and is responsible for more than seventy-five prints. Those on Ilford matt, P.O.P. number fourteen, and the rest are equally distributed between bromide and platinum. Thus the public who crowded the club-rooms on the opening day was able to judge the merit of the different effects given by various optical combinations, foci, and apertures, without being disturbed by doubts on the origin of the effect noticed. The pictures were divided into five classes—single anachromatic lens, symmetrical, adjustable landscape, studio telephoto lens (semi-anachromatic and anachromatic). Each combination had its separate panel, with title attached, and a special one was reserved for comparative examples demonstrating the result of correct and over exposure, incomplete correction and focussing, etc., etc.

The most crowded were those reserved to the symmetrical lens, which was to be expected from the handiness of the instru-

ment and its beautiful results. Thirty-three exhibitors in this class showed 140 prints. The adjustable landscape lens, though of quite recent date, has eight exponents with twenty-one prints; the single lens, the first of those constructed by Messrs. Pulligny and Puyo, gives sixty-one prints by eighteen exhibitors; the studio telephoto lens twelve prints by five exhibitors. Of course Major Puyo is at the head of the exponents of the new objectives in quantity and quality; while M. de Pulligny, busy chief engineer of the Roads and Bridges Department, only shows six prints. There are some most interesting pictures—M. Hachette taken on the banks of the Seine with the adjustable landscape lens, some figure studies by M. Pein d'Origine, Dubreuil, Schneider, Garnier, Besson, Vte. de Singly, Rolato Petion, Cte. de Montgermont, etc. The "adjustable landscape" examples by Major Puyo are most convincing; there is a softness in the gradation of distant planes that is distinctive of the lens employed. His large heads—some of them nearly life-size—taken with the studio telephoto lens, have lost all the harshness of outline that one generally associates with such productions, yet the drawing is firm and absolutely correct.

In fine, the anachromatic lens has just scored a victory, but one must not believe that because of this the cup will go to the fuzzy school, neither will it stay with the *f*/64 micrographer. The great majority of the pictures exhibited at our club, and especially those that won universal approval give the impression of sharpness, the suggestion of detail without being either sharp in definition or minute in analysis; and they are certainly not fuzzy—of that woolly fuzziness that all real artists detest—*not* true to nature—if you will put it that way, but true to the impression that nature gives us, which is better.

Theoretical explanations are being given in these same columns by Messrs. de Pulligny and Puyo, therefore I have only to speak about the practical results of these theories. Practical they undoubtedly are, in one sense of the word, though the question of cost has not been the leading idea in their evolution. In another sense, also, for the pictorial photographer who uses an anachromatic combination, such as a symmetrical one for portraits or the adjustable for landscape, is much nearer to the painter's rendering of nature than he was before. His work is begun for him by the lens; he will hardly finish it with his brains and fingers if he wishes to make his personal work—a picture—out of it; but even if he uses neither his portrait or his landscape will never be offensive through exaggeration of detail or distinctive focussing of planes.

This point—and it was not one of the least interesting of in the exhibition—was amply demonstrated by all the untouchable straight prints hung on the walls. Here—except, perhaps, the case of Fresson paper, which under expert hands allows of value correction, the quality of the negative and the balance of its composition were pitilessly exposed. Now and then an obedient lens had softened, according to its nature, the contour of an ill-posed arm or the complicated folds of a clumsily-dressed dress, but arm and folds remained with their ugly wrong line as a protest. Other men, like Puyo, for instance, passed unscathed through the ordeal. Of his work we had all seen the gum transcripts, but many of us ignored the negative, how faithful replica, minus the finishing touch of the author's hand, showed by elimination exactly how much had been due to the

... gum juiciness, and the cleverness of fingers in the other complete pictures. With some silver or bromide prints practically unknown authors the undeniable charm of the picture was proved to come wholly from the use of the anachromatic lens, for there is such a thing as *treatment*—though many photographers smile at the word—and the treatment, the *parti*

# MAJOR C. PUYO ON THE PROPERTIES OF ANACHROMATIC LENSES.

from a pictorial point of view the advantages conferred by the use of anachromatic lenses compared to corrected lenses are of two kinds:—

The pictures which they give have a higher value, esthetically. The simple construction of the lenses allows of greater focal lengths, and hence there is a better perspective rendering. We will consider these two aspects of the question in turn.

I presume that the reader has an elementary acquaintance with lenses, and that therefore he will understand that in the case of a lens uncorrected for chromatic aberration, the plate has to be

MAJOR C. PUYO. Self-portrait.

The above is a reproduction of the first portrait made with the single plano-convex lens. The original is whole-plate.

... at the focus of the violet rays representing the most actinic part of the spectrum. Under these circumstances the violet image is the sharpest, which produces the sharp definition on the plate; the other rays, blue, yellow and red, which do not come to a focus at this same point, infringe on the violet image. Thus the image of a point becomes a point surrounded by a halo: the image of a straight line becomes a line bordered on either side by a gradated region. Thus the image of a straight line is made up of:—(1). The violet image V V, sharp. (2). The unsbarr image of the blue rays which spreads from B B to B<sup>1</sup> B<sup>1</sup>. The unsbarr images of the yellow rays which spread up to Y Y, Y<sup>1</sup> Y<sup>1</sup>, and of the red rays which spread up to R, R<sup>1</sup> R<sup>1</sup> (Fig. 1). The effect of this double region of diffused light constitutes synthetical rendering. This double fringe of diffused rays simplifies the rendering of masses without altering their fundamental lines. And are not precision in the drawing, synthesis and simplification in the rendering the first conditions of art?

*pris* of these lenses, when there are no faults in composition and lighting to spoil things, will suffice to attract favourable attention, and cause a considerable degree of pleasure to those who know how to look at things. The first result is *pleasing*—that is the real way of expressing it, and to work on such a foundation is also a pleasure.

ROBERT DEMACHY.

Consider, for example, a surface made of very thin bands, arranged alternatively, black and white. A corrected lens will give a negative image of such an object, consisting of sharply defined regions, as in Fig. 2, which is supposed to represent a part of the negative greatly enlarged. If the lens, however, is anachromatic, the straight edge of the band A A<sup>1</sup> will be blurred. This blurred fringe will encroach on the white portion B B<sup>1</sup>, and will cover it if the breadth of this white band is about the same size as that of the blurred fringe. The fringe on the left hand of the band C C<sup>1</sup> will act in the same way in toning down B B<sup>1</sup>, and if the exposure be prolonged, B B<sup>1</sup> will be more or less tinted.

On the other hand, the quantity of light received on  $\alpha \beta$  and  $\gamma \delta$  being the same, the bands A A<sup>1</sup> and C C<sup>1</sup>, if equally exposed, will print less strongly.

Thus it will be seen that the square  $\alpha \beta \gamma \delta$ , instead of consisting of black and white bands, will tend to become a grey patch of tone midway between that and the white and black (Fig. 3).

FIG. 1.

FIG. 2.

FIG. 3.

Now, the synthesis which consists in replacing a varied surface by a continuous tone, the value of which represents the integrals of all the tones in that surface, is of the kind which we hold to be pictorial. Does a painter put into his landscape a house roofed with slates, some light, some dark, and others covered with lichen? He half shuts his eyes, and with one stroke of the brush sums up the whole effect of the roof in one tone which is a summary of all the tones in the roof. Suppose he has to paint a face covered with freckles. Again he half closes his eyes and mixes on his palette the mean tone which represents the skin. The anachromatic lens does the same.

From this explanation it will be understood that so far as relates to outlines the chromatic blur or diffusion softens the passage from one tone to its neighbour, thus assisting the figure to merge into the background. If the reader has noticed the way in which the painter Henner merges the outlines of his nymphs into the dark background, and the simple way in which he models his figures in full light, he will have a fairly precise idea of the effect of the anachromatic lens.

To sum up:—Chromatic aberration tends to give us simplification of surfaces without alteration of the drawing; this is our object. But it will do better.

The breadth, L, of the blurred fringe (Fig. 1) is proportional to the absolute diameter of the stop. It is equal to 1-100th of its diameter. Thus, if we consider a series of anachromatic lenses, having the same relative aperture, but with focal lengths in increasing series, the chromatic blur will increase in proportion to the focal length, and consequently will be greater, as the scale of the image is greater. Thus the rendering becomes simpler and broader, proportionately, to the size of the image. The value of such a relation, from an esthetic standpoint, will be easily understood. But the anachromatic diffusion is not only a useful agent, it is a docile agent, for we have at our disposal several means of regulating its action.

(1). BY DECREASING THE SIZE OF THE STOP.—The breadth of the blurred fringe (Fig. 1) is, as I have said, equal to 1-100th of the diameter of the stop. By decreasing the latter, we diminish the blur.

(2). BY ALTERING THE EXPOSURE.—Returning to Fig. 1 we see that the blurred outline is supplied by the less active rays, and, therefore, if we cut down the exposure, the red rays will not have time to exert their action, and the image, instead of spreading to  $R R, R^1 R^1$ , will spread only to  $Y Y, Y^1 Y^1$ . If the yellow rays are allowed sufficient time for their action, the chromatic blur will be still more restricted, viz., to  $B B, B^1 B^1$ . Thus the degree of synthesis will be proportionate to the length of exposure.

(3). BY THE PARTIAL CORRECTION OF THE ANACHROMATIC LENS.—For this reason one of the special lenses has been called the semi-anachromatic, the chromatic aberration in it being reduced about half to one-third the breadth of the blurred region, diminishing in equal proportion.

The advantages of the anachromatic lenses may be summed up as follows:—Drawing without hardness; blurring of details, and therefore suppression of retouching; unison of the figure with the background; breadth of drawing proportional to the scale of the image.

II.—Anastigmats, and even the portrait lenses of the Petzval type have much too short focal lengths in regard to proper perspective. If bad drawing and exaggerated perspective are to be avoided the lens must be placed far from the sitter, and thus the photographer is driven to the use of lenses of considerable focal length.

The simplicity of the anachromatic combinations supplies us with great latitude in this respect. A plano-convex lens of 16 inches focus, having a diameter of 4 or 5 inches, and working at an aperture of  $f/7$  or  $f/8$ , costs only a few shillings. The only limit is the exten-

sion of the camera. But this last restriction may be avoided by use of the telephoto form of the lenses.

We have worked out for the studio very simple forms of the telephoto lens of sufficient rapidity—the diameter of the front lens 4, 5, or 6 inches—and giving a range of foci which allows of taking heads life size at a distance of three or four yards.

For landscape work experience has shown us that the most useful focal lengths are those comprised between double the shorter axis of the plate and double the diagonal. A small telephoto lens, which we have named the “adjustable landscape lens,” has been therefore constructed and supplies all these useful focal lengths. It is of course necessary to draw out the extension of the camera, and the result focus is equal to length of the draw plus a few centimetres.

In the “adjustable landscape lens” a residue of spherical aberration comes into play in addition to chromatism. The effect of the former tends towards broadening the drawing so that in spite of a smaller diaphragm which must sometimes be used to get aerial perspective, the image remains soft and broad. This residue of spherical aberration gives the lens great depth. As a result several planes in a landscape decrease in definition regularly, and distance is particularly well rendered.

To resume, pictorial photography should find in the use of anachromatic lenses many new and valuable resources.

By courtesy of the Royal Photographic Society a collection of prints made with the various lenses here described, and arranged under my supervision, will be included in the next exhibition of the Society in London.

C. PUYO.

### M. LECLERC DE PULLIGNY ON THE LENSES.

THE BRITISH JOURNAL OF PHOTOGRAPHY, in its issue of January 6, last year, devoted several columns under the above title to the lenses, specially intended for pictorial photography, which my friend, Major Puyo, and myself have been attempting (since 1902) to add to the equipment of the photographer. One of the articles was a translation of Major Puyo's description of the new lenses. The other put forward some observations in regard to them, and drew attention to certain points which appeared to call for explanation. In the following article I propose to recall and amplify the information given by Major Puyo and to answer the questions which have been raised.

This further consideration of the subject seems to be justified by the fact that the new lenses have largely been taken up by the group of artist-photographers who are members of the Photo-Club of Paris, by whom the success of the new instruments has been demonstrated in the present exhibition at the Photo-Club. M. Demachy, who needs no introduction to English readers as a leading exponent of pictorial photography, reviews this exhibition with the authority which attaches to whatever he takes it upon him to write, and therefore it will be my care not to trespass on the ground which he will cover, but to confine myself to considering the lenses themselves.

These “artistic lenses” are called “anachromatic” to denote that they are not achromatic, just as “anastigmats” are so called to indicate the absence of astigmatism. The words “chromatic” and “stigmatic” could, of course, be used in the respective cases, but custom has already sanctioned the latter, and the former may therefore be adopted.

#### Anachromatic Lenses.

The anachromatic lenses are of a very simple kind. Several types of them have been made. Some consist of one single plano-convex or meniscus lens; others of two thin meniscus lenses assembled symmetrically; still others (the telephoto lenses) consist of a converging lens (plano-convex) and a diverging lens (plano-concave).

One special form designated by the English name, “adjustable landscape lens” has its purpose sufficiently indicated thereby. It consists of a converging and diverging lens after the manner of the telephoto form, and as it has only four reflecting surfaces gives exceedingly brilliant images.

These lenses are all made in crown glass, any ordinary crown lens glass being suitable for the purpose. Even the less commonly used “St. Gobain” glass employed for the manufacture of spectacles can be used. As the lenses have frequently very considerable focal length (20 to 40 inches), and as their aperture is usually  $f/10$  to  $f/5$ , their diameter is bound to be great—from 3 to 6 inches.

In spite of this fact the cost of the lenses is very small. The

plano-convex lens of St. Gobain crown,  $3\frac{1}{2}$  inches in diameter mechanically worked, costs only four francs to make; the meniscus of the same diameter costs five francs. The cost becomes greater with greater diameter of the lens, and it must be multiplied by three for genuine crown lens glass, and if the glasses are to be worked by hand.

All the lenses which Major Puyo and I have employed in investigation have been of St. Gobain crown and machine-worked. It is true that the St. Gobain works manufacture a glass specially adapted for spectacles, which they melt with special precautions. The pieces intended for our lenses were selected from the centres of large samples then moulded hot, and cooled with every care. Under these circumstances I have never seen any defect due to lack of homogeneity of the glass or to any other cause, and I have used lenses up to 6 inches in diameter.

Though the glasses themselves may be inexpensive, the mounting of such large glasses is costly. However, those who possess large portrait lenses can have the glasses removed, and on stating their size and positions to the makers of anachromatic lenses, may be supplied with glasses adapted to any particular portrait-lens mount. At the same time a black cardboard ring, of the same height as the lens previously used, is inserted to prevent the new ones from moving. The lens makers can supply rings of blackened copper for this purpose, on the necessary height being given them.

In certain cases the mounting can be adapted to receive the anachromatic lenses. The method to be followed will be found in a book, “Objectifs d'Artiste,” shortly to be published. The lenses thus be mounted by the photographer himself on the front of camera, and the expense of mounting reduced to about four francs for a lens of 16 inches focal length, an instrument which permits of every artistic portraiture being done. Thus any amateur who is owner of a camera taking plates  $7 \times 5$ , or whole-plate, is able to discover for himself to what extent the anachromatic lenses will assist him in portraiture.

#### Softness at Will

The chief characteristic of the lenses is the production at any aperture of an image of great softness in which, nevertheless, rendering of the features and of the expression is respected. Chromatic “fuzziness” by its nature, is not produced in the parts of the image which receive the least light. The deep shadows therefore preserve all their depth, and this chromatic fuzziness may not be ob-

\* The French word “flou” is thus rendered, though diffusion or softness are other appropriate synonyms.

ended with woolly diffusion due to errors in focussing or to the use of an R.R. lens, which suffers from spherical aberration.

According to the combinations employed, to the diaphragm, to the rate of exposure and the degree of correction, all imaginable varieties of fuzziness can be obtained, from a total destruction of definition suggesting the works of the painter, Carrière, to a minute amount of fuzziness—a mere *soupeçon* such as the professional photographer might offer in a portrait to the most Philistine of his customers.

from the sitter. He takes the nearer standpoint in order better to distinguish features—his eye not having the defining power of the photographic lens—but he mentally assumes a position more than double this distance.

To quote Charles Blanc:—"If a photographer wishes to portray a person without diminishing the parts removed from him, his standpoint should be at least ten yards from his sitter. When a painter cannot retreat so far, he obtains the same effect by a knowledge of

M. E. Turillon.

M. E. Morin.

#### MAKERS AND DESIGNER OF THE ANACHROMATIC LENSES.

between these two extremes are the coarse and pronounced effects reminiscent of the nude studies of Henner.

In every case the effect is to suppress or reduce details, the minute reproduction of which is the cause of the usual nagging character of photographs. Trifling defects of the skin disappear and the touch of the aid becomes superfluous, in the case of negatives in which a fair amount of fuzziness has been admitted, and lightened in the case of those in which an anachromatic lens, such as a professional photographer might use, has been employed. These two advantages—artistic effect and suppression of retouching—would seem to assure the success of the anachromatic lenses in the hands of artists, of professionals who are compelled to produce what their customers require, as well as of amateurs. The latter frequently produce photographs which are unsatisfactory to the sitters, chiefly for the reason that the amateur cannot retouch, and that the lighting in an ordinary portrait is almost always hard in its results. The anachromat does its work in retouching, its *estompage* corrects the hardness of the lighting, and hence it would seem that the amateur has a better chance of making a pleasing portrait with this lens than with any other.

#### Long Focus for Good Perspective.

Beyond this artistic effect and the suppression of retouching, the lenses have another advantage:—Practically they are the only ones available, at a moderate price, in focal lengths sufficient to realise the perspective which the eye sees, which artists adopt instinctively, and which the pictorial photograph lacks. The evil of the lens in perspective is its absolute truthfulness. Say you have to make a portrait of a soldier in uniform (the breast 20 inches across) placed half as wise to the line of sight. If your sitter is placed only one yard from the lens the image of one epaulette will be noticeably smaller than that of the other. At two yards distance the defect will not be so pronounced, but nevertheless, will be quite unpleasantly apparent. A painter, placing himself two yards from his sitter would draw his epaulettes almost the same size. At the most he would not make the rear epaulette less than 9-10th that of the one nearer to him. He would be assuming a point of view some four or five yards

perspective which enables him to correct what he sees and to make his drawing as though he were at the necessary distance."

We said ten yards, but if the model projects an arm or a leg in a direction towards or away from the camera, the point of view should be 15 or 20 yards. If he stretched towards the point of view, like Mantegna's "Christ," a distance of 30 or 40 yards should intervene. But, however, the considerable distances of ten yards and upwards refer to portraits of the full length figure in which hands, feet and shoulders can be at notable distances from a plane at right angles to their line of sight and parallel to the ground glass. In the case of a head or bust skilfully placed, the most prominent features of the subject relatively to its mean plane are considerably reduced, and experience shows that at a distance of 10 to 13 feet the perspective rendering is satisfactory. This distance is necessary, for whenever a head is photographed at a less distance than 3 or 4 yards the lens distorts the sitter, the nose becomes that of Cyrano, the lips those of a mulatto, whilst the forehead slopes back, and the ears are dwarfed in the distance.

#### Optical Conditions for Large Heads.

Professional photographers most frequently employ a Petzval lens known as "three-inch" or "two-inch," according to the diameter. These lenses supply heads up to the so-called carte size without it being necessary to overstep the distance of at least 10 ft., which should separate sitter and camera. But frequently the photographer will employ a lens of short focus and large aperture at close quarters for portraits of children. When the reduction in size is considerable the distortion is scarcely observable. But as soon as we photograph, with the same lens, a head alone, the defects can easily be seen. If under these conditions an enlargement is obtained direct the caricature will be striking.

We may thus assume that 10 ft. is the minimum distance at which to photograph. But if, in addition, we wish to make large heads, we soon see that we are forced to use immense focal length, lenses of corresponding diameter, and cameras of like proportions. Thus, at a distance of 10 ft., I wish to make a head one-third the size at an

aperture of  $f/8$ , I shall need a lens of 30 inches, 4 inches diameter, and with an extension of camera of 40 inches. For a photograph half-size, the figures will be:—Focal length, 40 inches; diameter, 4½ inches; camera extension, 60 inches.

The same inconvenience follows us in photographing so as to fill, say, a whole-plate,  $8\frac{1}{2} \times 6\frac{1}{2}$  inches, with the portrait of a person 30 ft. distant. In order to obtain an image one-tenth the size we should need a focal length of:—

$$F = \frac{30}{\frac{1}{10} \times 1} = 33 \text{ inches,}$$

and a camera extension of gigantic proportions.\*

To expose quickly, a relative aperture of  $1/9$  will be necessary, that is to say, a diaphragm of four inches and a lens of 4½ inches diameter.

The whole conclusion is that we should work at considerable distances, with long extensions, with large lenses and with long foci. Under what conditions can we obtain these essentials?

Distances up to 13 or 14 ft. may be assumed to be available in the case of the great majority of studios. The amateur working out of doors, with a head- and side-screens can produce all the forms of lighting which his fancy may dictate, and his exposures will be shorter than in the studio. The distance of the standpoint will not be an obstacle to him.

Nor will the camera extension be an insuperable difficulty. An ordinary landscape camera, about whole-plate in size, will have an extension of at least 24 inches, and usually the photographer possesses an enlarging camera with which he can obtain extensions from 24 inches to 5 ft.

#### Anachromat v. Anastigmat.

In regard to the choice of focal length, the conditions are not so satisfactory. With lenses of focus exceeding about 16 inches the optician experiences considerable difficulties in fulfilling the many and various perfections required of a modern anastigmat. These perfections, useful in making portraits or landscapes in small sizes, justify their existence in the case of lenses for large plates only for the purposes of copying plans and maps or for photographing a regimental group around its colonel. However, justified or not, these properties call for the most lengthy and arduous labours, for complex calculations, endless experiments, and highly trained workmen, all of which costs the lens-maker and the customer dearly. I have before me the catalogue of a noted firm which recommends for all-round purposes, including portraiture, lenses of aperture from  $f/3.6$  to  $f/5$  covering the entire plate without astigmatism and with extremely fine definition. For a plate  $7 \times 5$  inches, and focal length of 10 inches, the lens cost 535 francs. For a plate about "whole-plate" in size, the cost is 865 francs. For  $12 \times 10$  the cost will be 1,250 francs, and lastly, for a plate  $15 \times 12$  and focus of 24 inches, the price is 2,500 francs. It is a tidy sum of money, and I feel a certain amount of pleasure in saying that a double lens of the same focus and the same aperture,  $f/5$ , would cost, in the anachromatic series, about 100 francs. It would not be in any way comparable to the anastigmat except in rapidity, but it would possess other qualities, which, for artistic purpose, are to be preferred.

Difficulties of distance and of camera extension, together with high prices, combine to lead the photographer away from the use of lenses of long focus. The idea, more or less clearly defined, that he has all these obstacles in his way, persuades him to the view that, after all, perspective in portraiture is a Will o' the Wisp, that it is just as well to ignore it or make believe to ignore it. And then he forces his lens to do what is beyond it. He places it three feet or less from the sitter and obtains faces in which the right eye is much smaller than the left, of floors which appear inclined at 45 deg., and similarly in landscapes in which the distance is dwarfed into insignificance, and milestones compete with Mont Blanc for pre-eminence of height. Of all this the great public perceives nothing, because it does not observe anything until it is pointed out to it, and also because it has been so long accustomed to see false perspec-

tive in its albums and on its walls that use has become second nature and it accepts them as the truth.

Artists, however, have not been content. For æsthetic reasons they feel bound to work with a long focus, a demand on their purses which they can satisfy at small expense in the anachromatic ordinary or telephoto lenses.

A landscape camera will always permit of a focal length down to the shorter side of the plate, and for portrait lenses, intended for these instruments, we would select focal lengths of at least the same magnitude. On a triple-extension studio camera we should not hesitate to place a lens of 24, 30 or 40 inches focus. We should not hesitate for the reason that a single plano-convex lens of 40 inches focus would cost a few francs, whilst an anastigmat of the same focal length would mean the price of an estate in Beauce, and, moreover, would yield a result quite foreign to our purpose.

The extension of our camera is too short? The addition of a single diverging lens will convert our objective into a telephoto lens, permitting us, if we will, to take life-size heads at 10 to 15 feet.

The portraitist with pictorial intent will thus acquire, at little cost, an immense latitude in his work. He will place his model as far from the camera as his studio permits, and, taking his position behind the focussing screen, will adjust the size of the image to his liking by a turn of the screws actuating the back and front of the camera. His procedure is a contrast to the method of the user of a lens of fixed focus, who must wheel his camera to and fro to the discomfort of the sitter.

In outdoor photography the difference is no less marked. While one worker is at trouble to replace one lens by another from his outfit, his more discreet companion will have only to turn the screws of his "adjustable landscape lens" and, according as he wishes, will fill the whole or part of his ground glass with the subject before him.

To pass to a description of the anachromats we must say that the single lenses are of considerable rapidity ( $f/9$ ), and the double combinations of twice this speed, viz.,  $f/5$ . They thus permit of ordinary work in a studio. In regard to the telephoto lenses the rapidity will be proportional to the square of the diaphragm of the front lens, as in all lenses of this kind.†

If one wishes the head as large as possible (one-third to one-half natural size), and the distance from the sitter to be great (10 to 15 feet), one must provide a telephoto lens by taking an instrument of large diameter as front lens. The old 4-inch, 5-inch, and 6-inch portrait lenses are admirable for this purpose, as are also anachromatics of the same diameter.

#### Focussing.

Focussing with the anachromats should be done carefully as with all lenses, if the maximum sharpness is desired in one part of the image rather than in another. The best plan is to focus on printed characters (the title of a journal) held by the sitter and with a medium stop. A larger or smaller stop is then inserted as may be desired before exposing the plate. A small correction must be made in the focus before exposure, but the correction does not need to be very exactly made, nor need it involve calculation of any sort. Several ways of making it are dealt with in the forthcoming "Artistic Lenses."

The theory of the anachromatic lenses, the practice with them, and their advantages in photography, were published for the first time by the author as follows in a memoir in the "Bulletin of the Photo-Club," in March, 1902,‡ and some time later the lenses were tried and adopted by the members of this artistic society. Major C.

\* I have given an English name to this lens in acknowledgement of the admirable landscape work of photographers in Great Britain, and for the further reason that the day of its production, in June, 1905, coincided with the public expression of the "entente cordiale" a sentiment which has been identified with my own warm feelings for England and for many English friends.

† In the little work, "Artistic Lenses," I have shown that in the telephoto lens, as in all optical instruments, the illumination of the image, and, therefore, the rapidity is proportional to the expression:—

$$\left(\frac{d}{aG}\right)^2,$$

where  $d$  represents the diameter of the diaphragm of the front lens,  $a$  represents the distance of the object from the front lens, and  $G$  is the scale on which the image is reproduced, i.e., the ratio 1:0 of any dimension in the image to the corresponding dimension in the object.

‡ Le Flou chromatique. "Bulletin du Photo-Club," March, 1902.

\* The following is the formula for solving problems of this kind:—To reproduce an object on a scale of  $1/n$ , it must be placed at a distance  $D$ , from a lens of focal length,  $f$  such that

$$D = (n+1)f \quad (a),$$

and in this case the camera extension will be:—

$$T = f + \frac{1}{n}f \quad (b),$$

Puyo, whose beautiful productions in portraiture are well known, has used no other since this time. He submitted new combinations to systematic investigation, which have entirely confirmed the theoretical predictions and have fixed the forms of lenses. Major Puyo embodied his technical and artistic results in articles in the "Revue de Photographie,"\* and in May, 1904, he arranged in his studio an exhibition of prints by the new lenses, which were classified according to the method of production. The remarkable results impressed amateur and professional photographers who visited the exhibition.

Lastly, at the Congress of the Union of French Photographic Societies at Nancy in July, 1904, Professor Wallon presented a lengthy communication on the anachromatic lens† and discussed fully the scientific theory of these instruments and their applications in photography.

It now remains for me to answer the interesting questions raised in reference to the anachromatic lenses by "The British Journal of Photography" last year.

### The Price of the Lenses.

Of this I have already spoken; the cost of the lenses in machine-worked St. Gobain glass is ridiculously low. In hand-worked crown glass it is much more. It is also much more for lenses of large diameter mounted in copper, but even under these conditions a symmetrical anachromatic lens will be one-fourth or one-fifth the price of an anastigmat of the same focus. If the worker is content with a single plano-convex lens, working at  $f/9$ , and suitable for portraiture of the head and the full figure as well as for landscape, the mounting can be dispensed with, and such a lens in machine-worked St. Gobain glass, if made by a good firm, answers perfectly. Major Puyo, I myself, and friends of ours have never employed any other. In this case the expense is reduced to the purchase of the lens, that is, to 4 francs for a lens of  $3\frac{1}{4}$  inches diameter and 16 inches focus; to 6 francs for one of 4 inches and 20 inches focus, and to 16 francs for one of  $6\frac{1}{4}$  inches diameter and 32 inches focal length.

### The Novelty of the Anachromatic Lenses.

In articles on this subject I have mentioned the former use of lenses uncorrected for chromatic aberration. The sets of spectacle lenses such as those of Comte d'Assche are an example of the use of these lenses:—the periscopic lens of Steinheil is another. But both these forms of lens are employed at a very small aperture,  $f/40$ , and less, and little or no correction is made for the chemical focus. The small working apertures greatly limit the usefulness of the lenses. The anachromatic lenses, on the other hand, can be used at  $f/9$  in the case of the single lenses, and at  $f/5$  in the case of the doublets. They bear the same relation to the periscopic lenses of Steinheil as do the portrait eyescopes of Voigtlander to the ordinary wide-angle rectilinear. It will not be denied that there is a difference between these lenses and that it is important to provide one rather than the other. The anachromatic lenses can be applied to purposes which were beyond the less rapid predecessors, but with the employment of a large aperture comes the necessity of making the chromatic correction with accuracy, and I think I may claim to have studied this part of the question thoroughly, and to have worked out a novel, theoretical and practical solution.

I have shown also by calculation that for very small diaphragms and exact correction, the "fuzziness" of chromatic aberration disappears entirely. The "fuzziness" of the spectacle lenses is due to spherical aberration, and the periscopic actually does not give any fuzziness at all. It seems that one might employ a good R.R.

If in place of making an exact correction, one made none at all, the effect would be the same as if a slight alteration in the focus obtained with a corrected lens were made before exposure. The result consists in a displacement of the maximum of sharpness, which removed before or behind the subject which is focussed. If the diaphragm is sufficiently small the depth of field is great, and the defect is not perceptible. If the diaphragm is large enough for the defect to be seen the parts which are not sharp suffer a general and uniform confusion of outline which is not at all pleasing. Hence it

comes about that certain zones of the photograph are too sharp, whilst others are not sharp enough; and the zone in which the diffusion is altogether pleasing is too restricted for us to arrange the composition in it, and the total result is *nil*. In both cases the effect is quite different from that produced by chromatic diffusion.

### Can the Corrected Lens Imitate the Anachromatic?

Can the same results be obtained by suitably employing rectilinear or anastigmat lenses? From what I have said it will be seen that it is not enough to displace the focussing screen after focussing. The "out-of-focusness" thus obtained is of a kind which I have described already as uniform and destructive of the drawing. With anastigmats with iris diaphragm I do not see that we can do more than this, for even at full aperture their corrections of chromatism and spherical aberration are usually perfect. The same question may be asked in reference to the old rapid rectilinears and single lenses. As a rule these lenses are so made that they can be used with a stop a little larger than the one for which they were intended for the proper correction of their aberrations. But under these circumstances they often have a small chemical focus, and if the larger diaphragm gives less sharpness it is more because of this insufficient achromatism than through the very slight effect which the spherical aberration can produce for an enlargement of the diaphragm in the ratio of 2 to 1. If a print be carefully examined it will be seen that the fuzziness is nothing else than our enemy the diffusion produced by putting out of focus. To make good use of these lenses it is necessary to make an exact chromatic correction, which amounts to bringing the lenses into line with the anachromatic theory. In "Artistic Lenses" will be found some experiments on an old, so-called, achromatic, landscape lens; it was  $3\frac{1}{4}$  inches in diameter and 20 inches in focal length, and was intended to be used at an aperture of  $f/30$  or smaller. Used without a stop at all, say at  $f/5$ , but with exact chromatic correction, it was found to produce very soft portraits of the anachromatic quality.

One word more in reply and I have finished. The author of the article concludes by saying, in effect:—"I prefer a corrected lens, for by suitably employing it I obtain results equivalent to those of chromatic fuzziness, and the same lens would supply me with critically sharp photographs when I had need of them, whilst the anachromatic lens is useless to me in such a case."

I believe that such a view involves a double error. I have shown that the corrected lens cannot give the chromatic softness. I would add that by using a sufficiently small stop in an anachromatic lens, all diffusion disappears, and the results are as sharp as may be desired. At  $f/10$ , and still more at  $f/15$ , the results with a symmetrical anachromat can scarcely be distinguished from those of a rectilinear. The anachromat can be used for excellent instantaneous work, and is better for the special purpose of hand-camera work than a badly corrected lens. The adjustable landscape lens when stopped down to  $f/45$  will serve for the copying of plans over a critically flat field.

In thanking "The British Journal of Photography" for the opportunity of stating the claims of the anachromats, it may be mentioned that Major Puyo and myself have no interest in the production of these "artistic lenses" other than the pleasure of contributing to the progress of pictorial photography. We have published in the "Bulletin of the Photo-Club," and in other publications on photography, all the formulæ relating to the lenses, so that no patent can be taken out as to their principle, and that all opticians can manufacture them. Those who desire to undertake the manufacture, and all those who wish to investigate for themselves the properties of the lenses, may consult the work, "Objectifs d'Artiste,"\* to which we have referred already. Moreover, two French firms of high standing, one in Paris and one in the provinces, are now in a position to supply the lenses and all the information relating to them. We wish those interested all the pleasure in this new branch of photography which we ourselves have discovered.

## COLOUR PHOTOGRAPHY.

### A LUMIERE ONE-LENS ONE-EXPOSURE CAMERA.

THE detailed description of a one-lens one-exposure camera for three-colour work is the subject of a recent French patent, No. 350,004 (June 20, 1904), by MM. A. and L. Lumière. According to the specification, the purpose of the invention is to obtain simultaneously with one lens, three images similar in size and lighting. The principal part of the apparatus is a divider, Fig. 1, formed of two sheets of glass,  $d$ ,  $b$ , at right angles to one another and placed behind the lens  $o$ , in the position shown in Fig. 2. The function of this divider is to direct the image formed by the lens into three directions so as to permit of the separation of rays by filters suitably placed. The divider may be placed as shown in Fig. 1. The sheets of glass  $b$ ,  $d$ , are silvered on their surfaces next the lens in parallel bands  $a$ ,  $a$ , the width of these being equal to their distance apart, so that each sheet of glass is divided into alternate and equal transparent and reflecting surfaces. On one of these glasses  $b$ , these bands are perpendicular to the intersection  $i$  of the glasses; on the other,  $d$ , they are parallel to the intersection. The divider thus formed is placed behind the lens  $o$ , so that the axis of the lens is perpendicular to the intersection  $i$  of the two sheets of glass, and so that it forms equal angles with each.

The rays  $x$ ,  $y$ , which are transmitted by the lens, fall on the front surfaces of the glasses  $b$ ,  $d$ , and are primarily divided into two equal parts, one of which traverses the transparent parts of the sheets of glass and falls on the posterior halves  $x_1$ ,  $y_1$  (Fig. 2) of the glasses. The other, which is reflected by the silvered bands, encounters the anterior halves,  $x_2$ ,  $y_2$ . The rays which arrive direct on the posterior part of the glasses are divided into two equal parts, the  $y_1$ ,  $x_1$ , one which passes through the transparent parts and arrives without reflection at  $y_4$ ,  $x_4$ , on the surface  $m_1$ , the other part, which is reflected by the silvered bands, arrives at  $y_5$ ,  $x_5$ , on the surfaces  $m_2$ ,  $m_3$ . The rays which are reflected on to the back of the two glasses  $x_2$ ,  $y_2$ , are also divided into two equal parts, one of which traverses the transparent and reaches  $x_6$ ,  $y_6$ , on the surfaces  $m_2$ ,  $m_3$ ; the other part, which is reflected by the silvered bands, is sent back through the lens and is useless. In practice, the surfaces  $m_1$ ,  $m_2$ ,  $m_3$ , are mirrors (at an angle of 45 degrees), which reflect the images on to a sensitive plate  $p$ , placed, as shown in Fig. 3, parallel to the axis of the lens.

The necessary colour-filters,  $e_1$ ,  $e_2$ ,  $e_3$ , are placed in the path of the rays corresponding to each image, and the three fundamental negatives are obtained on  $p$ . Ordinary positives can be made from them by any of the well-known methods. If in place of the sensitive plate,  $p$ , the triple positive images are inserted, and the necessary filters placed in the path of the rays, the lens  $o$  will give by projection or direct vision one image, reproducing all the colours of the original.

Instead of using the glasses with silvered bands one may use coloured glasses without the silvered bands. Fundamental colours must be chosen for these glasses, such as yellow and blue, blue and red, or yellow and red. If, in Fig. 4,  $j$  is a yellow glass, and  $b$  a blue glass, the rays  $x$ ,  $y$  transmitted by the lens and falling on the yellow glass  $j$ , are divided into yellow rays which pass through this glass, and into rays of the complementary colours which are reflected and traverse

the blue glass  $b$ , which is in their path. This glass constitutes part of the coloured medium the absorption of which is supplemented by the violet filter  $e_3$ . These rays form an image on the surface  $m_1$ , and this is a negative image of the yellow rays. The rays which fall on the blue glass  $b$  are also divided equally into blue rays which pass through this glass, and into complementary colour rays, which are re-

lected and traverse the yellow glass which is in their path. This screen constitutes a part of the coloured medium, the absorption of which is completed by the orange screen  $e_2$ , and these rays form an image on  $m_2$ , and this is the negative image of the blue rays. Finally the yellow and blue rays which pass through the two sheets of glass, traverse a third green screen  $e$ , which forms with the two sheets of glass a colour absorptive medium which gives the image on the surface  $m_3$ , this being the negative image of the red rays.

### THE TECHNICS AND PRACTICE OF THE LUMIERE STARCH GRAIN PROCESS.

IN the latest issue of the "Agenda Lumière," a collection of facts and formulæ, compiled and published by the Lumière Company, of Lyons, is an article on the forthcoming process which may be translated in full in view of the assurances from Lyons that the sensitive plates are to be on the English market in a month's time. The article repeats certain facts, but it gives a graphic account of the process by which M.M. Lumière have at length succeeded in reducing colour-photography to the simplicity of ordinary exposure and development.—Eds., B.J.P.

\* \* \* \* \*

#### Principle of the Process.

If on the surface of a sheet of glass, and in the form of a thin single film, a collection of microscopic elements, transparent and coloured reddish orange, green, and violet are spread, we shall find if the

spectral absorption of these elements are correct, and if they are in correct proportions, that the film thus obtained, when examined by transmitted light, will not appear coloured; this film will only absorb a fraction of the transmitted light.

The luminous rays traversing the fundamental screens, orange, green, and violet, are reconstructed and form white light if the sum of their surfaces for each colour, and the intensity of the colouration of the constituent elements exist in proportions which are well known. The thin trichromatic film thus formed is subsequently coated with a panchromatic emulsion.

If now such a plate be submitted to the action of a coloured image, taking the precaution to expose it through the back, the light rays traversing the fundamental screens, will, according to their colour and the colour of the screens they encounter, suffer a variable absorption. We thus realise a selection by the microscopic elements which en-

ables us, after development and fixation, to obtain coloured images, the colours being complementary to those of the original.

### How the Complementary (Negative) Image is Formed.

If we take, for example, a part of the image coloured red, the red rays will be absorbed by the green elements of the film, whilst the violet and orange elements will transmit them. The panchromatic film, therefore, will be acted upon under the orange and violet elements, and the green elements will appear after fixation because the panchromatic film has not been acted on under the green elements.

Development will reduce the silver bromide of the film and mask the orange and violet elements, and the green elements will appear because the silver bromide has not been reduced under them. We have then in this case a residue coloured green, which is complementary to the red rays we have been considering. The same phenomena will occur with the other colours; that is to say, with green light the green elements will be masked, and the film appear red. In the case of yellow, the violet image will appear, and so on.

It will be seen that a negative in these complementary colours ought to give, with a plate prepared in the same way, positives which would be complementary to the negatives, that is to say, positives which would reproduce the colours of the original.

One might also, after development of the negative image, omit the fixation, and reverse the image by one of the well-known methods so as to obtain a positive direct which would present all the colours of the original object.

The difficulties which we have encountered in the application of this method are numerous and considerable, but after laborious researches we have surmounted them, and the Lumière Company are preparing to supply such plates.

It will be sufficient to briefly indicate some of the most important conditions which had to be fulfilled to prove how delicate the problem was.

### Technical Problems of the Process.

We had first to find a film formed of microscopic filters, orange, green and violet. It was necessary that this film should adhere to its support, be very thin, and that the colouration of the elements of which it should be composed should be rigidly determined as regards intensity and exactness of colour, and as regards the number of elements to a given area. The colours must be stable, they must not run, and there must be no superposition of the coloured filters, and no interspaces. Finally, the film has to be covered with a varnish having the same index of refraction as the grains.

It was essential that the sensitive film should be orthochromatised—that there should be no false rendering of colours—and that this orthochromatism should be in relation to the nature of the emulsion and the colour of the elementary filters. The film of emulsion should be of a special nature to prevent diffusion, and the manipulations, development and exposure should be appropriate to these preparations.

The simple enumeration of one of the conditions will serve to show how much care and method was necessary. First, potato starch had to be separated by instruments specially devised for the work, for the grains have a diameter of from 15 to 20 millimetres. These grains are divided into three lots, which were respectively stained reddish orange, green and violet, by the aid of special colouring matters.

The coloured powders thus obtained were mixed, after complete dissociation, in such proportions that the mixture did not show any residual colour. The resultant powder was then brushed on to a sheet of glass covered with a sticky substratum. With suitable precautions, we shall obtain a single film of grains which touch each other without any superposition.

The interspaces had to be filled up by a similar process of powdering so that no white light was transmitted. This obscuration is effected by means of an extremely fine, black powder of wood charcoal, for example.

We have thus formed a screen on every square millimetre of surface of which there are eight or nine millions of small elementary grains, orange, green and violet. The surface thus prepared is protected by a varnish, having about the same refractive index as that of the starch grains, a varnish as impermeable as possible, on

which finally a thin film of sensitive panchromatic emulsion of silver bromide is coated.

The exposure is made in the ordinary way in any camera, but in every case taking the precaution to reverse the plate, so that the rays from the lens traverse first the coloured particles before reaching the sensitive film. It is also necessary to interpose a special yellow screen to compensate for the excessive activity of the violet and blue rays. The absorption due to the interposition of the coloured elements, although a very sensitive emulsion is used, necessitates a somewhat longer exposure than usual. Still, it is possible to obtain results in sunshine in one-fifth of a second with a lens working at  $f/3$ .

Development is effected as in an ordinary photograph, and if one is content to fix the image, the result will be, as we have already pointed out, a negative presenting by transmitted light the colours complementary to those of the object photographed. But it is preferable to re-establish the order of the colours on the same plate by chemical reversal of the image. For this the silver reduced by the developer is dissolved by a suitable bath, and then the remaining silver bromide is developed, producing a black image which is complementary to the negative obtained by the first development.

It will thus be seen that the manipulations are simple and only slightly different from those of ordinary photography.

### A MAKER OF GUM PAPER ON THE PROCESS.

EVEN the best workers in "gum" often go astray because they desire to get great depth of colour, and, on account of this desire, they sometimes use too much pigment, with the result that they get a very steep scale of tones as well as a gritty surface. Too much gum again—or what is the same—gum too strong, usually gives chalky high lights. The sensitiser cannot be too strong, however, and a saturated solution is usually used. The exposure (writes Mr. A. W. Hill, in the "Secretary's Letter" of the Scottish Photographic Federation) must obviously be such as will suit the process of development that the worker prefers or finds himself best able to accomplish.

For an ideal gum print—which is to preserve most of the tones of the negative, besides possessing that subtle something which only gum prints have, and which is usually termed a "running over" of the pigment—just sufficient exposure must be given as will keep the details in the high lights. If less exposure be given, the result is chalky whites and no detail in the shadows. If more then, the half tone and shadows are clogged up and the luscious ideal print is not. Gum printing, being very similar to water-colour drawing, the swelling of the film and the exudation of the unaffected pigment is the ideal method of development. There are other methods, not so much ideal, but eminently practical all the same for special effects, and these, especially brush development, should be utilised where necessary and desirable. But it will be found that brush-developed prints never have the luscious appearance that is the charm of the perfect gum print.

Always use some sort of actinometer when printing, because not only do you then know exactly when exposure has been correct, but if, by accident, over-exposure should occur, you will be forewarned and therefore forearmed when you come to develop.

During the experimental—or shall we call it apprenticeship stage?—it is a good plan to use up any spoiled prints by trying to modify the tonal values with the brush, by vignetting large heads, putting in clouds, or causing the distance to appear really distant, and not merely, as usually happens in the ordinary negative, simply smaller. It is in these valuable methods of control that gum scores over all other processes, and as they cannot be used successfully unless after considerable practice, it is essential that, along with perfection of coating and development, after-work on the print should have a great deal of attention. Indeed, unless the worker feels he can help his print after development, or during the same, he need not go to the trouble of becoming an adept at the preliminary stages. At the same time, once a worker really begins to get good results in gum, the process has such a fascination for him that he seldom altogether deserts it. And when he realises the extent of "help" he can give his negative by working on the print, his art-education has fairly begun, and in a short time he has placed a tremendous gulf between his old work and his new.

Possibly "the man in the street" will not appreciate your work. Never mind. No one takes his opinions or beliefs in art from the general public. Indeed the applause of the public so much wooed by some photographers should rather be avoided, for there lies the downward path to the realms of the "cheap and nasty."

## TWO ENLARGING QUESTIONS.

IN the course of an article in the "Photo-Era" on a number of practical matters relating to the making of enlargements, Mr. Edward S. King, of the Harvard Observatory, mentions two points which may be quoted as being novel to some who have had a good deal of enlarging experience. In focussing an enlargement, said Mr. King, it had been found by Professor W. H. Pickering that bad definition is sometimes valuable

Fig. 1.

Fig. 2.

for destroying the grain of a negative. Figures 1 and 2 show the image of a double star enlarged in focus and out of focus, the enlargement being the same in both cases. The silver particles which appear prominently in the first photograph are almost obliterated in the second.

The question of what exposure to give is frequently a perplexing one, although an old operator will be able to make a close estimate by noting the brightness of the light on a dummy plate. All persons, however, cannot turn their eyes into light meters, and some better means of measuring the light through all its transitions is

Fig. 3.

desirable. It will not always do to expose a trial plate, as the conditions may change completely before it can be developed and examined. A simple test is to interpose a lighted candle in the beam of light from the lens and note the shadow of the candle itself as cast on the dummy. This effect is shown in Figure 3. By moving the candle toward the dummy, a position is found where the light from the candle just obliterates the shadow cast by the light from the lens. The distance of the candle from the dummy is a measure of the light, and the exposure is proportional to its square. For example, I found for a certain class of work with Seed process plates that squaring the distance expressed in inches, and dividing

by 4, gave the exposure in seconds. The relation of the exposure in seconds to the square of the distance in inches is easily found by trial, for we can use the candle test with exposures obtained by any method, and determine the ratio from the best results. The kind of candle is not material so long as we use the same for all our experiments. There is some difficulty in noting just where the shadow disappears, and different eyes may vary in fixing the exact point. In general, a gentle lateral movement of the candle will enable one to see the shadow better, and make the observation of the disappearance more accurate. If the light from the lens is too faint to cast a shadow of the candle at a reasonable distance from the dummy when the aperture to be used for the enlargement is in place, we may increase the aperture for the test and allow for the change in the computation. This method of finding the exposure, if not exact, nevertheless affords a better approximation than given by the unaided judgment.

## Exhibitions.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE seventeenth annual exhibition of the South London Photographic Society was opened at the Public Baths, Camberwell, last Saturday, March 3, and closes to-morrow, Saturday, at 10 p.m. The energy of the South London members finds its expression in the large number of frames on the walls, nearly 550, besides lantern-slides and stereoscopic. The exhibition would gain, we think, from a somewhat more rigorous selection, especially in the open classes, where the inducement to hang the work of members is not so great as it is in the case of the classes which are made up solely from members of the society. Architecture, always a strong feature at South London, is also a notable feature of the present exhibition, especially in the open class, which is one of the strongest in the show. The open landscape is large, but rather weak, and a goodly number of the photographs might well have been spared. In Class A, portraiture, figures, studies, etc., by members, the first bronze plaque goes to "A Bit of Old Glastonbury," by W. Llewellyn White, a clever combination of a figure, standing in an archway, and architectural surroundings. The second award is to a picturesque rendering of Staple Inn, by Gideon Clark, whose photograph might have just as suitably been classed with landscape, for the figures, though excellently placed in the composition, are not the chief object of interest in the picture. We do not care for Dr. Evershed's portrait of Mr. E. T. Holding, which, to our mind, gives a wrong suggestion of physique. Other work in this class which is worthy of notice is "A Canny Customer," by Miss Maude A. Craigie-Halkett (No. 15); "His Daily Toil," by T. E. Walter (No. 2), and No. 47, "A Dutch Figure Study," by W. F. Slater. Class B shows the good architectural photography which we have always associated with the South London Society, and includes some very fine technical work. The awards go to C. J. T. Walford, "Light and Shadows" (No. 72), and to E. R. Bull, "Wren's Cloister, Lincoln" (No. 84). Class C, devoted to landscape, contains some exceedingly good technical work though in this class and in the architecture we are impressed by the fact that the leading South London members hold somewhat too closely to traditions of composition and technical quality. The result, in our judgment, is the absence of work which appeals strongly to the imagination. In the architecture we can discover no photograph which has the charm for us possessed by many of Mr. Fredk. H. Evans' photographs of such subjects, and the same criticism may be applied to the landscape section. The first bronze plaque goes to E. W. Taylor for a breezy seascape, "Away to the Fishing Ground" (No. 177), which owes a good deal of its success to the way the fishing boat is placed in the space of the print. The second award falls to a photograph by G. R. Nicholls, "Evening Glow" (No. 158), which impresses us as a case of super-chromatic correction. The planes of the subject could have done with a greater suppression of tone as they recede from the camera. As it is, the windmill in the distance is too near the foreground in tone. "The Haven under the Hill" (No. 124) suggests a tiny seaport, but turns out to be a

village in a vale. We forgive the mis-used title, for the photographer has rendered the subject effectively. The photograph would be better still on a larger scale. In "The Crane," Dr. Evershed gets some good feeling into a picture of a dock wharf in November, and his success is the more notable in its environment of factual prints. "Snow and Fog," a picture of the tops of suburban villas in the snow, however, is quite ordinary and uninteresting. The class devoted to photographs made on society excursions is the least satisfactory in the hall, and confirms the general belief that for pictorial work the worker had better be alone.

In the open class for portraiture and figure studies the silver plaque is gained by C. B. Howdill's well-known "Modeller." Three other awards suggest that the judges were in pensive mood, for their awards go to "Sad Tidings," "Sad Memories," and "Memories." However, things are not as bad as they appear, for the first-named, by C. Peacock, might just as well have been entitled "Gossip," and the second, an old man in a church porch, by E. A. W. Moore, does not particularly bear out its title.

In the landscape open class the first award goes to Basil Schön for a strong treatment of a roadway in winter (No. 448), and the second to a familiar picture, "Tugging Home," by W. Clayden. We should like to find a word of commendation for "A City Highway, Custom House, Dublin," by Mrs. D. Mahoney, and we must also not omit the Edwards' Memorial Competition for the best reproduction in monochrome of a coloured original. Mr. E. J. Wall was the judge in this section, which has been a feature of the South London Exhibition for some years past, and has thoroughly outworn its technical interest. We suggest that the competition might be modified to keep in step with current progress, and actual reproductions in colours of a coloured picture be demanded. Such a contest would be true to the spirit of the original plan of the competition, and would possess a great technical interest.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between February 19 and 24:—

**DARK-ROOM LAMP.**—No. 4,306. An improved dark-room lamp. James Rankin Garrow and Houghtons Limited, 88, High Holborn, London.

**COLOUR PRINTS.**—No. 4,476. Process of producing multi-colour prints. John Bachmann, 18, Southampton Buildings, London.

**TELEPHOTO LENSES.**—No. 4,523. Improvements in photographic tele-objectives. Carl Zeiss, Jena, Germany.

**PRINTING FRAMES.**—No. 4,527. Improvements in photographic printing frames. Leon Faure, trading as Guy and Co., Temple Buildings, Albert Street, Nottingham.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**PIGMENT PRINTS.**—No. 12,867, 1905. The process has for its object a simple manufacture of carbon papers, and in order to attain this another vehicle than gelatine must be used, such as will permit the development on the side which is exposed to the light and will produce direct pictures. Such a vehicle, which permits the development on the exposed side has been discovered in emulsified casein and soap. If the materials are emulsified in a suitable manner and mixed with the required pigment and gum arabic an emulsion is obtained which can be poured on to a support of gelatine, and will become sensitive to light in a solution of bichromate of potassium in such a manner that on subsequent exposure to light, the parts acted on by light are rendered insoluble in warm water. The excess of colouring substance is then removed by washing with water, and the picture

is developed. This new vehicle of the pigment, which does not combine so intimately with the latter as gelatine, gives a different appearance to the print. The print has no homogenous surface, but appears granular in a strong light and irregular. In the deeper shadow where the effect of light was stronger, the grain decreases, however, and disappears in the deepest shadow. This grain, i.e., perfectly white spaces adjacent to the black pigment, gives a highly plastic effect to the picture, which has not been obtained in any other manner, and is a characteristic point of the vehicle. Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—Pigment printing process consisting of an emulsion of casein and soap as a vehicle and binding means for the layer of pigment, with or without the addition of the usual admixtures, substantially as described. Fell and James, for Emil Bühler, Schneisheim, Germany.

**PROJECTION APPARATUS.**—No. 6,169, 1905. The apparatus consists of an arrangement whereby transparent objects such as ordinary lantern slides and opaque objects (photographic prints, etc.), may be projected in rapid alternation by the same apparatus. As shown in the figures the construction of the apparatus in-

cludes a side projection lens 18, which receives the image of the opaque object 52, and transmits it to the screen by reflection from the mirror 19. The specification describes the carriers per-

mitting the expeditious change of transparent and opaque objects. Albert Thornton Thomson, 15, Tremont Place, Boston, Suffolk, Mass, U.S.A.

**PHOTOGRAPHING THE EYE.**—Referring to the letter of Mr. Arthur Whiting, and our comment upon it in our issue of February 9, "The Dioptric Review" says:—"We should suggest that the principle of telephotography be employed. If it be true that the condition of the iris is a reflex of certain bodily conditions, then the subject is one that will well repay investigation. The method of Dr. Dimmer and Dr. Thorner is, however, for taking photographs of the interior of the eye and not the exterior. Such photographs have been taken with exceptionally large pupils, e.g., those of cats under the influence of atropine."

A RETIRED photographer (aged 70) named Albert Betts, late of Treherne Road, Mortlake, met his death last week on the South-Western Railway. The deceased was found dead on the line close to Richmond Station, where, it is supposed, he wandered without realising his danger.

## New Apparatus, &c.

The "Autokon" Enlarger. Sold by Messrs. John J. Griffin and Sons, Ltd., Kingsway, London.

The distinctive feature of this enlarger is the automatic focussing obtained by an arrangement of levers geared to the front and back of the camera, whereby the movement of the former, necessary for sharp definition at any given enlargement, is obtained from a curved slot in the baseboard. The enlargement thus remains in focus as

its size is increased or diminished by actuating the pinion which moves the camera. The method should save a good deal of time in making a number of enlargements. In other respects the "Autokon" is a well-equipped instrument. The easel is provided with removable panel in place of which a carrier is inserted when slide-making by reduction. The negative carrier is adjustable all ways for correction of errors in verticality or for selection of part of a negative, and the illuminant may be either oil-lamp or incandescent gas. The prices of the enlarger range from £3 5s. to £9 9s.

A NEW form of mount for the Dallmeyer portrait lenses has just been introduced by the makers, Messrs. J. H. Dallmeyer, Ltd., New-man Street, London, W., with the purpose of facilitating the use of the lens in giving diffusion of focus. As is known to many users of the Dallmeyer lenses—we are informed that many, on the other hand, are ignorant of it—the posterior cell can be unscrewed and thus

produce a general distribution of focus throughout the various planes. This adjustment has hitherto had to be made by removing the lens from its flange, or by inserting the hand in the bellows of

the camera, in both cases an operation which is not at all expeditious. The new mount is made (as shown in the figure) so that the turning of the lens barrel displaces the posterior cell, and the amount of the turning—through one or more revolutions—is noted on the mount by bringing an appropriate part of the 4-section scale opposite the catch on the flange. On the catch being released the rotation of the lens tube unscrews the lens from the flange in the ordinary manner. The lenses are now issued in this improved mounting at the same prices. Existing lenses can be adapted at a small charge. It will be understood that this movement does not prejudice the use of the lens for critically sharp work, but it places the photographer in the position to produce softened definition, and to repeat these effects with certainty. This step on the part of Messrs. Dallmeyer will thus be noted with interest in connection with the articles on the advantage of chromatic diffusion which appear from several French authorities elsewhere in our pages this week, although it is not to be assumed that the effect obtained is the same as with the so-called "anachromatic" lenses.

### CATALOGUES AND TRADE NOTICES.

The newly-issued 1906 catalogue of Messrs. J. Lancaster and Son, Ltd., which reaches our table from Colmore Row, Birmingham, maintains the traditions of this well known firm, which, thirty years ago, commenced the popularisation of amateur photography. The present list of 84 pages is an eloquent testimony to the energy and enterprise with which during this period the affairs of the firm have been prosecuted, for it describes cameras and other apparatus, which embody the latest conceptions in photographic instruments, and are offered at prices which place them at the disposal of the great middle-class public. Messrs. Lancaster place their total sales of cameras at 400,000, and the list before us, by its variety for selection, justifies the firm in its appeal to photographers of all descriptions.

Messrs. Houghtons, Ltd., send us the classified list of their clearance sale, in which they are offering a great variety of apparatus and materials.

A list of trade work reaches us from Messrs. Flamank and Towns, send, 69, Whitehead Road, Aston, Birmingham, a firm which makes a speciality of bromide enlargements within twenty-four hours of order, and is also establishing a connection for half-tone blocks, dry mounting. The firm has also a number of special lines for amateurs.

A FIRE took place last week on premises occupied by the Midgley Photo Company, Loughborough. The outbreak was caused through the accidental overturning of an oil-stove, but was not serious.

LA CHAMBRE Syndicale des Fabricants et des Négociants de la Photographie, 54, rue Etienne-Marcel, à Paris.—The following are the recently elected officers:—President, Charles Mendel; Vice-President, Grieshaber; President of the Manufacturers' Section, P. Mercier; President of the Dealers' Section, Faine; General Secretary, Reeb; Secretaries of the Sections, Bondon and Trambouze; Treasurer, Bœspflug; Recorder, Daynes; Librarian, Duplouch; Delegates to the Caisse, Degen and Korsten.

MESSRS. B. J. Edwards and Co. desire us to make known that Mr. H. A. Crabb will in future represent them in the North of England, Scotland, and Ireland.

BOLTON Amateur Photographic Society.—The exhibition which is to be held on the 18th, 19th, and 21st of April promises well. Through the courtesy of the committee of the Northern Photographic Exhibition the Society has been able to arrange that all pictures intended for that exhibition will be forwarded and delivered by special messenger (free of cost to the exhibitor), so as to be in time for judging at Manchester. It is to be hoped that many of the best workers of the day will take advantage of this arrangement and show at both exhibitions. The exhibition secretary is Mr. W. Midgley, of 9, Ducie Avenue, Bolton.

TESTING Gelatine.—A paper before the New York Section of the Society of Chemical Industry, printed in the Society's Journal for February 28, deals with the measurements of viscosity, etc., necessary for the valuation of glues and coarse gelatines. The author, Jerome Alexander, announces the prosecution of other tests to be applied to photographic gelatines in the laboratories of the National Glue and Gelatine Works.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
.....	Aberdeen Photo Art Club .....	"Enlarging." Mr. D. Duff.
.....	Colne Camera Club .....	Miscellaneous Slides. Mr. E. A. Spivey.
.....	Aberdeen Amat. Photo. Assn. ....	Members' Slides.—Critic, Mr. J. Milne.
.....	Bromley Camera Club .....	"The Photographic Lens." Illustrated. Dr. John Scott.
.....	Leicester Lit. and P. Society.....	Election of Officers. "Toning of Lantern Slides by Variation of Exposure and Development." Demonstrated. A Member. Royal Photographic Society Affiliation Prize Lantern Slides, 1905.
.....	Loughton Photographic Society .....	Demonstration. Mr. Stearns.
.....	Photographic Society of Ireland .....	"Photography as an Aid to the Study of Archaeology." Mr. T. K. Hackett.
.....	Sutton Photographic Club .....	"Bromide and Gaslight Papers." Messrs. A. P. Hoole and E. De Clifford.

.....	Chelsea and District Ph. Soc. ....	

**SHANGHAI PHOTOGRAPHIC SOCIETY.**—Dr. Patrick gave a lantern lecture in the Union Church Hall on January 25, on "British India: Races and People." During the evening a few slides from negatives taken in Nanking Road during the recent riot were shown, by kind permission of Messrs. Max Nossler and Co., owners of the negatives.

**BURTON-ON-TRENT NATURAL HISTORY AND ARCHEOLOGICAL SOCIETY (PHOTOGRAPHIC SECTION).**—The secretary of the above section is now Mr. George Moore, 254, Branston Road, Burton-on-Trent, to whom all communications should be addressed.

## ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, March 6, the President, Major-General Waterhouse, I.A., in the chair.

Mr. E. J. Wall gave a demonstration of pinatype and the Rotary Company's superimposed carbon colour tissues, explaining first, by means of a triple lantern, the difference between additive and subtractive colour processes, and the necessity for using red, yellow, and blue pigments. Briefly, pinatype is a process of colour printing in which three transparencies are made from the three colour negatives, and these printed on to gelatinised plates sensitised with bichromate. The print plates thus obtained are stained up in red, blue, and yellow dyes, and then successively superimposed on to damp gelatinised paper. Stress was laid on the necessity of obtaining very soft transparencies in the first place, and also on transferring the yellow image on to the blue, as otherwise it was rather difficult to secure accurate register. The constituent images were shown, together with the final print. The process is also applicable to lantern-slide making, and the three images are successively printed on to bichromated gelatine, after each exposure the image being stained and coated afresh with gelatine. The yellow image could also be used as a cover glass by making a reversed positive, and printing from this and staining up. For making the reversed positive a method was described in which the image was printed on to bichromated gelatine and stained up in a new dye, which gave a good black-brown image. Incidentally some good transparencies were shown prepared by this method in green, blue, olive, and brown, and the images were naturally remarkable for the absence of grain and great transparency of the shadows. In dealing with the carbon tissues, which are coated on thin celluloid and exposed through the back, the lecturer stated that he had abandoned the maker's instructions and used a 2 per cent. solution of ammonium bichromate and dried the films during the night. An actinometer had to be used, and, having once determined the necessary insolation for the blue image, the yellow film takes one tint less and the red one tint more. A finished print and also printed and developed tissues were handed round. The tissues had to be mounted, the yellow first, with an 8 per cent. solution of gelatine. Mr. Wall stated that neither process presented any particular difficulty, and both were open to considerable modification of results, as in pinatype the prints could be reduced or strengthened in any one or all colours, and that precisely the same effect, though to a less degree, was possible with the carbon tissues by using longer or shorter development of the exposed tissue.

A discussion followed, in which Messrs. Snowden Ward, O'Farrell, F. C. Lambert, and J. S. Teape, took part.

**SOUTHAMPTON CAMERA CLUB.**—On Monday evening Mr. Horsley Hinton, who is one of the Presidents of the Club, lectured on "Pictorial Photography." Mr. Hinton first dealt with his subject by way of precept and advice, and later illustrated his views with convincing slides. The lecturer defined "pictorial photography" as being the attempt to convey by means of photographic apparatus and means an artistic impression received by a worker. He pointed out at the beginning that ordinary photographic apparatus was not necessarily, as at present used, the most suitable for the purpose, nor did photography as taught to most beginners necessarily lead to really artistic work. The picture which might be properly so called should have something which answered to body and to spirit. It was the business of the picture-maker to secure, if possible, upon his plate a result which should correctly render the impression which he had received from his subject. But if he had failed to do this, and yet had in his negative the recorded image or body of his picture, it was justifiable and desirable to put into it the motive or spirit, the impression which had induced him to make his exposure. Mr. Hinton expressed the opinion that far too much was photographed. The exposing of plates on merely pretty scenes was deprecated, and the necessity for a motive in the picture, some combination of line or design or some attempt to express emotion in some degree, laid down. The searching for a composed subject in laboured fashion was pointed out as a far less satisfactory method than the acknowledgment of the principle that the worker should wait until some subject should strike his appreciative attention. Mr. Hinton was most cordially thanked at the conclusion of his valuable lecture.

**BOLTON AMATEUR PHOTOGRAPHIC SOCIETY.**—On February 22 Mr. Von Schevon, of the Bayer Company, Limited, demonstrated the working of "Pan" paper. One of the most attractive features of this paper is the great ease with which a variety of different tones and colours may be attained by merely varying the exposure and developer. This property, it must be understood, does not leave anything to chance, as by a careful adherence to the makers' instructions any desired result may be achieved. The first essential is to ascertain the correct exposure for a black tone and then to increase the exposure according to the tone desired, and dilute the developer proportionately. Fixing from five to fifteen minutes in a 10 per cent. solution of hypo and washing are to follow.

## Commercial & Legal Intelligence.

**THE first meeting of the creditors interested under the failure of Francis Edwin Ellis, photographic artist, "Ivycroft," Stockfield Road, Streatham Hill, S.W.,** was held at the offices of the official receiver for the Wandsworth district, York Road, S.E., on the 1st inst., but the proceedings were of a purely formal character, as there were not enough creditors present to form a quorum, consequently the meeting was adjourned until the 9th inst.

**HEAVY Sentence on a Bradford Photographer.**—At the Bingley Police Court on February 28 Arthur Lister Bradley, photographer, of Picton Street, Bradford, was charged in three cases with obtaining money by false pretences, and a similar charge was preferred against Lawrence Boulger, canvasser, of Bradford. Mr. C. P. Cass, of Keighley, appeared on behalf of Bradley. The case was outlined by Inspector Kemshell, who stated that on January 24 the men were paid 2s. 6d. by a young lady named Miss Maud Ellis, of Crossflats, for a dozen picture postcards of herself and a cousin, photographed together. On Christmas Day they obtained 1s. 6d. from Mrs. Sarah Barker, of Eldwick, and 2s. 6d. from Fred Hanson, market gardener, Eldwick, also for picture postcards from photographs which were then taken. In each instance a receipt was given for the money paid, signed with the name "A. Bradley," and giving the address "Lumb Lane, Bradford." In no instance, however, were any photographs supplied until after the proceedings had been commenced against them, but he (the inspector) understood that a number of persons had since received the photographs for which they had paid. He added that he had witnesses to speak to nineteen cases of this character, some of them going as far back as June last year. Evidence was then given in the three cases in connection with which specific charges had been laid, and afterwards other evidence was called to show that the method followed had been practised in a number of other instances. Three cases at Cullingworth, where the photographs were taken in June and August last, were brought forward, and in each instance the parties heard nothing more until Monday of this week, when they were supplied with the photographs for which they had paid previously. In two other cases—one at Bramhope and the other at Lindley, near Huddersfield—no photographs had been supplied at all, although in the first instance the order was given at the beginning of September last, and in the other about the middle of December. Mr. Cass, for Bradley, submitted that although there might have been a breach of contract on Bradley's part, there had been no false pretences. The photographs had actually been taken, and the prisoner was in possession of the negatives, and the fact was that he had simply neglected to produce the photographs and had gone on taking fresh orders instead of completing those previously taken. Since the proceedings were commenced he had, acting upon his advice, got out as many of the old orders as had been possible, and the whole of them would be completed as soon as possible. The accused had been in business in Bradford for about fifteen years, and had never been in trouble before. Boulger urged that he had been simply in the employment of Bradley as canvasser, being paid a commission upon the orders obtained. The Chairman (Mr. J. Roberts) said the bench considered the prisoners guilty, and it had been a question whether they should not send Bradley to prison without the option of a fine. However, they had decided to fine him £7, with the alternative of two months' imprisonment,

on each of the three charges, whilst Boulger would be fined £1, or ten days' imprisonment, in each case.

**EMPLOYERS' LIABILITY.**—At the Islington County Court, before his Honour Judge Edge, Charles Weeks, through his father, James Weeks, 16, Goswell Terrace, Goswell Road, sued Jacob Phillips, photo mount manufacturer, 18, Roscoe Street, Golden Lane, E.C., under the Employers' Liability Act, for £78, as damages in respect of personal injuries sustained. Mr. Lever was counsel for plaintiff, and Mr. Green for defendant. The case came before a jury. Plaintiff, who gave his age as 18, said he was formerly in the employ of defendant, his duty being to work a machine for cutting out cardboard mounts. He worked the machine as instructed by Mr. Mann, the foreman. It was worked by the foot pedal, and the mounts were laid on a piece of cardboard and pushed underneath the knife or cutter by his hands. Occasionally, after the knife had come down, the cardboard would stick, and on the 5th of July last, when the accident happened, he put his hands on the cutter in order to loosen the cardboard. Whilst so doing, the fingers of his right hand slipped, with the result that the two first fingers were badly injured, and subsequently an amputation of one finger had to be performed. His wages at the time of the accident were 10s. per week. Replying to a question, plaintiff admitted that on one occasion the foreman complained about him taking his eyes off the machine whilst working it. Mr. Phillips, for the defence, said he had had the machine in question for twelve years, and had always used it for the purpose of cutting photo mounts. That was the work on which plaintiff was engaged, and the system was to use two cardboards, one as a carrier and the other to cut through. That was the system generally used throughout the trade. Alfred John Mann, the defendant's foreman, who instructed plaintiff in the working of the machine, said he also had distinctly told him never to put his hand on the cutter. Plaintiff had a habit of looking round when working the machine, and witness had spoken to him about it. The carrier-board (a specimen of which was produced in court) was sufficient for plaintiff to do the work with safety. Plaintiff admitted to him that the accident resulted from his own fault. James Lee, an engineer, said machines of that sort were not guarded. He had seen a number of them at work, and for that class of work he had always seen the cardboard used. When doing labels a metal plate would be used, but not for photo mounts. The jury, who went to defendant's premises and inspected the machine during the luncheon interval, gave a verdict in favour of plaintiff, damages £10.

**PLEASURES of the Canvassing Business.**—David Clarey, 44, labourer, Bargoed, and Elizabeth Clarey, 43, married, Bargoed, were summoned at Caerphilly Police Court on Tuesday for assaulting Clement Stone, a Cardiff photographer, and David Clarey was also summoned for damaging two photographs, value 16s. Mr. Herbert Samuel, Cardiff, prosecuted. It appears that in the course of his business Mr. Stone called at defendants' house and arranged a deal with the male defendant. Suddenly, however, defendant picked up the picture and ran to the other end of the table, saying, "Now, you can do as you like. You will have to summon me in the County Court ere you can get anything from me." Complainant, after remonstrating, said he would have to inform the police. Clarey then became enraged, struck him, and said, "If you don't clear out I will murder you." Clarey was alleged to have rushed at Stone with a poker, and then, as he raised another frame to protect his head, defendant struck at him with it, and the iron crashed through the glass and wounded him on the head. Mrs. Clarey also rushed up and dealt him a blow with an ash-pan, after which complainant sent Miss Elizabeth Davies, one of his assistants, for the police. Whilst he was outside his two frames were thrown out on the road, and the door of the house then closed. Mrs. Esther Evans said that she was present when complainant brought the picture, and demanded 16s. 6d. for it. Complainant "gave a lot of impudence," and was then ordered out. She saw Stone strike Clarey on the head with the frame held in both hands, and although the row lasted ten minutes she remained in the back room. The Bench said there had been an assault committed, and fined the male defendant 10s. and costs, or seven days, and the wife was fined 5s. and costs. For the damage the male defendant had to pay 15s., and deliver up the enlargement when called for.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### COLOUR-PHOTOGRAPHY.

To the Editors.

Gentlemen,—In Mr. Otto Pfenninger's reply to my letter of last week he has taken a wide survey of the cameras of the type under discussion. I may say at once that his history of patents for reflector cameras is approximately accurate, but does not affect the statement of Mr. Pfenninger, which I challenged. That statement was "that all cameras of the reflector type have failed to produce triple negatives of equal size." Because of this failure, Mr. Pfenninger informs us, patents have been allowed to lapse. I have not allowed my patents to lapse, because, among other reasons, my cameras have not failed in this respect; nor do I purchase identity of size, as Mr. Pfenninger suggests by reducing the angle of view to 5–10 degs.

Mr. Pfenninger amends his statement, in view of this last consideration. He now says: "If glass of 2mm. thickness is used for the reflectors, and if an angle of view of not less than 25 degs. is permitted, not one of the above now known reflector systems will give negatives for accurate superposition for printing methods."

I again challenge the statement most emphatically, and say that with an angle of view of over 35 degs., and with screens and reflectors exceeding 2mm. in thickness, and not optically worked, my camera "will give negatives for accurate superposition for printing methods."

It is true I do not ask Mr. Pfenninger for the optical solution of this—according to Mr. Pfenninger—optical impossibility, I am content with the accomplished fact. It is said that when George Stevenson made a steam engine capable of running forty miles an hour, a certain mathematical professor at one of our universities demonstrated to a mathematical certainty that such a speed was impossible for any locomotive.

I am quite content for optical theorists to prove the impossibility of my results to their own satisfaction, but I will submit, gentlemen, to such a practical test of the accuracy of my statements as is asked for by Mr. Pfenninger, namely, the production of actual negatives, even not smaller than half-plate size."

I forward for your inspection such a set of half-plate negatives taken in my Camera Patent, No. 4,290, 1905.

I am willing, gentlemen, to abide by your judgment as to their identity of size, and it is demonstrable that they were taken in a camera with an angle of view equal to 30 degs. This should be a sufficient proof to convict Mr. Pfenninger's statement of inaccuracy. An inaccuracy presumably arising from false theory, and perhaps a pardonable ignorance of crucial facts.—Yours faithfully,

36, Craven Park, Willesden, N.W.

EDWIN T. BUTLER.

March 5, 1906.

[Mr. Butler's negatives reach us as we go to press. We have only time to confirm his claims, and must postpone further reference until next week.—Eps. B.J.P.]

To the Editors.

Gentlemen,—With reference to Mr. Otto Pfenninger's letter in your last on p. 178, it would be as well to point out that in "La Triplique Photographique des Couleurs et l'Imprimerie," by Alcide Ducos du Hauron, Gauthiers-Villars, 1897, p. 217, he says:—

"20. Appareil à trois miroirs minuscules.—Le 17 décembre, 1885, je pris à la préfecture d'Alger un brevet d'invention (No. 173,101), aujourd'hui périmé, pour cet appareil, etc."

This your correspondent could not find.

Again, on p. 231 of the same work Du Hauron describes the diatropic method, with one objective and superimposed films.

At the close of the above book the author gives a list of his patents, communications, and work, and this includes the following:—"I have not had time or opportunity to turn these patents up,

but in all probability they will be found in the Patent Office Library."

"Decembre 15, 1874.—Brevet français de 15 ans, sous le No. 105,881: chambre noire héliochromique ou appareil photographique destiné à produire simultanément trois ou plusieurs épreuves d'un même sujet.

"Septembre 17, 1895.—Brevet français de 15 ans, sous le No. 250,802: Polyfolium chromodialytique: Livre à feuillets transparents constitué par une alternance d'écrans colorés et de plaques ou pellicules sensibles, au moyen duquel s'obtiennent simultanément, dans toute chambre noire, les trois phototypes destinés aux tirages photographiques en trois couleurs."—Yours faithfully,

E. J. WALL.

Sidcup, Kent, March 5, 1906.

### CONSTANT DEVELOPMENT FACTOR UNDER VARYING TEMPERATURES.

To the Editors.

Gentlemen,—It may interest your correspondent, "Q. S.," and others, to know that there will shortly be communicated to the Royal Photographic Society a further paper on this subject in continuation of the former one, by Mr. Howard and myself, which will, I hope, give him the information he requires on this subject. It is much to be wished that plate manufacturers could be induced to mark on their boxes the sensitometric constants, including the temperature co-efficient of each batch of emulsion for the particular developer recommended by them.—Yours faithfully,

W. B. FERGUSON.

Hotel Bristol, Arosa, Suisse.

March 3, 1906.

### THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION IN PARIS.

To the Editors.

Gentlemen,—My first answer to your unfavourable note in "Ex Cathedra," referring to the Second Paris International Exhibition of Photography, 1906, you inserted in that part of your paper reserved for correspondence.

Under the same title, "Ex Cathedra," you again refer in your No. 2390, 23rd February, to the same subject, publishing reports from your correspondent that are still more unfavourable than the first ones. This persistent hostility compels me to ask you to publish my reply in the same place that you have used for your fresh attack, namely, "Ex Cathedra."

The Second Paris International Exhibition of Photography, 1906, has the support of all the State Establishments, depending on the following Ministers:—Ministers of Commerce and Industry, de l'Instruction Publique, des Beaux Arts, des Travaux Publics, des Colonies, de la Justice; also the following National Establishments:—L'Imprimerie Nationale, l'Observatoire National, Conservatoire National des Arts et Metiers; and the following Museums of State:—The Louvre, Cluny, Trocadero, Versailles, etc.; Les Museums de la Ville de Paris (Cernuci, Carnavalet, etc.), Le Museum, le College de France, etc.

Under these circumstances it is very evident that the abstention of those societies and syndicates you have named is of no importance whatever, all the more as they do not prevent anyone from participating on his own account.

These groups have no power to keep their members from joining the exhibition. They refuse to join the exhibition *as bodies*, nothing more, and the best proof I can give you that they cannot compel their members not to join is that those houses which you yourself pointed out as keeping back (and which I do not want to name) have actually entered into negotiations with me at the present time. Your informant is certainly deceiving you. I flatly deny his statements, and in the interests of your own countrymen I would strongly advise you to hear both sides of the question before running down such a large undertaking, which it is my right and duty to uphold by all means in my power.—Yours faithfully,

L. GASTINE.

12, Place de Vaugirard, Paris.

Commissionnaire Général.

P.S.—I add to this letter a translation, which will help you to understand it, but it must be clearly understood that I hold myself responsible only for the French terms and their meaning.

[M. Gastine must surely know that the action of the "Chambres

Syndicales" was officially announced, and was commented on in the French photographic Press. Our paragraph of February 23 was simply the announcement of the fact, and our own deductions from it. If those deductions are wrong we are alone responsible. We have no desire or reason to be antagonistic to the proposed exhibition, and though we cannot depart from our custom of inserting letters in the usual place, we refer to the above communication from M. Gastine on the first page of this issue.—Eds., B.J.P.).

#### ENCLOSED ARC LAMPS.

To the Editors.

Gentlemen,—With reference to the article on "Enclosed Lamps and Photography," we would point out that the Janus Company, for whom we act as sole agents, have supplied such lamps for some time past, with highly satisfactory results.—We are, dear sirs, yours faithfully,

DRAKE AND GORHAM, LTD.

66, Victoria Street, Westminster, London, S.W.

March 5, 1906.

#### HALF-DAY CLOSING.

To the Editors.

Gentlemen,—Photographers have many troubles, but to use an Irishism the most of them are pleasures.

Now a mixture of both is the trouble in the question of why we do not fall in with the system adopted in many districts of a general half-day holiday. I am more concerned now with the middle-class establishment, in which I group my own business, and am inclined to think we ought to consider our young people and let them off at the same time and day that assistants in other businesses in the neighbourhood are free, because there are many arrangements made on this particular day by rail, boat, and other companies for this class of customer.

Many of us are granting our assistants time off upon various days in the week, such as many young people are having, viz., beginning on Wednesday and only finishing on Saturday. This plan at times is very inconvenient and not satisfactory to the young people concerned.

There is a fear existing that we shall lose something by it, but I think that is a fallacy. Some believe that assistants from other houses reserve themselves for a Wednesday or Thursday (whichever the closing afternoon is) sitting, and that if they are not open, the probable sitter will visit a neighbouring studio. I have come to the conclusion that assistants do not choose their half-days for any such purpose, and I know that this class of sitter in my district has no difficulty, and gets out in the early morning or in the dinner hour. Now, of course, the closing of one's business and leaving four or five other studios open close by, is out of the question, but if all the photographers in the neighbourhood agreed to close upon the usual half-holiday, then there is no question of losing business, and it is very soon understood by your customers that you are closing for the sake of your assistants. In my young days I never knew what it was to have a half-holiday. From the age of 17 to 30 I never took part in any outdoor sport, and was kept going from nine in the morning until all hours in the evening.

The place of business can be closed easier than in years gone by. Some will say the printer cannot possibly get off. I see no reason at present why he should not. "Where's there's a will there's a way."

Then why not fall into line and see what can be done in your own neighbourhood?  
Brixton, S.W.

R. LANG SIMS,

Member of P.P.A. Committee.

#### THE EXHIBITION OF COLOUR-PHOTOGRAPHY.

To the Editors.

Gentlemen,—I gather from last week's BRITISH JOURNAL OF PHOTOGRAPHY that you propose disbanding your very valuable collection of photographs in colour, but it appears to me that it will be a public calamity to do so. Twenty years hence the collection will be of immense value historically, and to every teacher or lecturer the loan of them would be of the greatest value in illustrating the

development of colour processes. Personally, I think it will be a thousand pities if a strenuous effort is not made to keep the collection intact. Doubtless many of the gentlemen whose kindness enables the exhibition to be held will be willing to present their specimens if a sufficiently important home is provided, and so far as financial aid is required in purchasing where necessary, and preserving them, I have no doubt whatever that it would be immediately forthcoming. If only in justice to those who have spent so much labour in producing the examples they should be kept as records of progress and to show what excellent results have been obtained at the present time in spite of the many technical difficulties with which the subject is surrounded.—I am, dear sirs, yours faithfully,

The Polytechnic Institute,  
309, Regent Street, W.

HOWARD FARMER.

[Mr. Howard Farmer's suggestion that the present collection of examples of colour-photography should be preserved intact is one which, of course, must depend for its execution first upon the exhibitors. Most probably a proportion of the exhibits, large enough to be representative of the whole, could be obtained. We shall be glad to hear the views of exhibitors as regards the establishment of the collection permanently.—Eds., B.J.P.).

## News and Notes.

IMPROPER Postcards.—The police court reports of the past week show that magistrates are determined to deal severely with offenders under the Obscene Publications Act, and though the publishers of the cards have so far escaped unscathed, the list of convictions should deter dealers from touching anything which offends against conventional ideas of decency. The sentences which have come under our notice include:—

Two months' imprisonment in default of payment of a £10 fine.

Three months' hard labour.

£5 5s. fine, and £3 3s. costs.

£2 fine, and £1 19s. costs, or a month.

In these cases large numbers of cards were ordered to be burned, and in another instance where 40,000 cards had been seized, no order was made, as the defendants consented to have the cards destroyed.

THE Free Portrait Swindle.—It is satisfactory to find that photographers of standing in their districts can rely on the co-operation of the local press in making known the fraudulent character of the so-called "free portrait" dodge. Thus we see in the "Hackney and Kingsland Gazette" a letter on the subject from Mr. F. A. Bridge, the well-known secretary of the Photographic Convention, which is worth quoting as a reasonable statement of the case:—"Sir,—As I have lately had several callers to enquire why I have not sent the enlargement as promised, or to ask for the return of the original, it is evident the free portrait swindle is going on in this neighbourhood, and someone is using my name and address in connection with it. I shall therefore feel obliged if you will allow me, in the interest of your readers, to say, that I have nothing to do with anything of the kind, and do not employ canvassers for any purpose whatever. I must candidly confess I have little sympathy for those who are taken in by the free portrait swindle, because they evidently are too thoughtless to ask themselves why someone of whom they know nothing, and who knows nothing of them, should be so anxious to present them with a large photograph. It is apparently the old story, viz.,—promise to make an enlargement for nothing, and charge as much for a rubbishy frame as any respectable photographer would charge for the whole thing. There have been several convictions lately in regard to the free portrait swindle, and if I can get hold of the culprit or culprits who are going about using my name and address, there will be others, or it will not be the fault of yours truly." F. A. BRIDGE."

Mr. A. C. Baldwin, who for some years past has demonstrated products of the Paget Prize Plate Co., Ltd., has joined Messrs. Wellington and Ward in a similar capacity.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Hannam, Windsor Road, Oldham. Photograph (Combination) of Werneth (Six Views).

Javis, 45, Coulston Road, Lancaster. Photograph Group of Generals Mends and Kelly, with Officers and Guests. Photograph of Old Colours of 1st Batt. "King's Own" Royal Lancaster Regiment. Photograph of Lieuts. Conran and Somerville with Old Colours.

Pottle, Eastbrook, Wimborne. Photograph of the Meet at Criche House Wimborne.

H. Franklin, 56, High Street, Slough, Bucks. Photograph (Flashlight) of the Slough Amateur Dramatic and Operatic Society Performing "The Mikado." Ingham, Winton House, Ashton-on-Mersey, Cheshire. Photograph of H. Hardy, Esq.

### DRAWING REGISTERED:—

Locke, 58, Haverstock Road, Knowle, Bristol. Drawing entitled, "The Boy with the Nuts."

**DIAPHRAGM NUMBERS.**—(1) I have a lens (of French make, I believe) marked 0.25, 0.30, 0.50, 1, 2, 4, 8, 16. I am told 1 corresponds to  $f/10$ . Can you give the other equivalent stops? (2) I have seen a notice somewhere of a "sodium flame" lamp. Can you tell me where to get particulars? It allows the rapid printing of P.O.P.—3 JAYS.

1) The lens is marked according to the International Congress of 1889; 1 is  $f/10$ , and the other numbers are proportional to the exposure required. Thus 2 is  $f/14$ , 4 is  $f/20$ , 8 is  $f/28$ , and 16 is  $f/40$ . (2) We have no knowledge of the lamp, and we certainly cannot imagine that a "sodium flame" would be of the slightest use for printing on P.O.P. You must be confusing the lamp with those of the enclosed arc type. See our last issue.

**ND J.**—The form of studio advocated in H. P. Robinson's "Studio and What To Do In It" is as effective to-day as ever it was, and we do not think any other design is considered superior by practical authorities. Of course, adjoining buildings and the direction of the available light frequently necessitate modifications, and a studio is often what is possible rather than what is desired. Of the two sketches you enclose A is preferable, but we should be inclined to increase the slope of the glass by having the ridge nearer to the 4ft. 6in. wall. This greater slope has several advantages—there is more room for a large background, the roller blinds work more easily, snow does not lodge so readily, and the rain water is shot off more rapidly, with correspondingly diminished risk of a leaky roof. We are averse to the much flatter roof which you show in the B sketch, and the separate side and top lights would necessitate two distinct sets of blinds. The roof, having unequal sides, requires to be carefully constructed to ensure sufficient strength; but your architect will no doubt see to this.

**ERENCE BOOKS.**—I require a reference book on photography, and desire to have either in India or from a European bookseller. The book may be such that it may enlighten me on reference the full explanations of all the technical terms and photographic

expressions. I know some of the reference books, but I do not know whether they will serve the purpose. I therefore note them down and request you to let me know whether they will do for my desire. (a) "Cyclopædia Photography," by E. L. Wilson, Ph.D.; (b) "Photographic Reference Book," by W. A. Watts, M.A.; (c) "The Encyclopædia of Photography," by Walter E. Woodbury; (d) "Dictionary of Photography," by E. J. Wall.—F. B. Z.

Certainly (d) (the latest edition) is the best of the volumes you name, and we would also recommend to you "Instruction in Photography," by Sir W. Abney, 7s. 6d.; and "The Science and Practice of Photography," by Chapman Jones, 5s.

**SILVER PAPER.**—I should be glad if you could give me a formula for silver printing paper requiring only washing to finish it.—H. H. URRY.

The only practicable process we can suggest to you is the Kallitype, which is strictly an iron process giving a silver image. You will have to fix in hypo, and we think you will find this operation indispensable to any process. You will find full instructions on Kallitype in "The Photo-Miniature," No. 47 (6d.). Let us hear from you if we can assist you further.

**THE HALF-TONE PROCESS.**—Would you kindly inform me what is the best book to get on the half-tone process, as I am desirous of going into that line of business?—INQUIRER.

"The Half-Tone Process," by Verfasser (Iliffe and Sons, Ltd., 5s.).

**THE RIGHT TO PUBLISH.**—I have taken a few photographs of a church, interior and exterior. Do I need any permission to publish them as postcards? I have made enquiries—some say I can, while others say I cannot.—FRANK E. JACKSON.

Certainly you can, so long as you have not been paid by anyone for taking the photographs. The copyrights are yours, and you should register them. Have you read the article on this question in the current "Almanac"?

**SPORTS.**—A reflex camera is very largely used—in fact, we should say it is almost the invariable rule for press work of subjects other than those in extremely rapid movement. A lens of aperture  $f/4.5$  to  $f/5$ , in conjunction with one of extra rapid plates, is the common practice in making the best of gaslight. For subjects such as bicycle races, etc., at close quarters, a direct camera of the folding focal plane type is probably better. You would do better with metal or pyrocathechin for this class of work.

**JAMES E. ANDERSON.**—The firm is no longer in existence.

**CHAS. MARSHALL.**—1. The stains you obtain are due to the precipitation of the earthy salts in the ordinary tap water you use. If you want to use ammonium picrate, you must not only wash your plates in distilled water, but use distilled water for your solution. We should strongly advise you to use tartrazine, which gives better rendering with less exposure. 2. Yes, you can obtain it from 6, Harp Alley, London, E.C.

**POSTCARD NEGATIVES.**—1. The best way to letter negatives for postcards in P.O.P.? 2. Can you give me the address of firms who supply machines for that purpose? I often see foreign photographs with good letterpress on the bottom, giving name of places, etc. I require something like it, as I find writing on film is not good enough.—P. Y. R. O.

1. The titles are photographed down to the size required—a good many made at one exposure on one plate—and then the negative is cut into strips and each title stripped off and transferred to the postcard negative, a small strip of which underneath the picture is cut out to receive it. This is necessary when adding a title to print in black on a white ground. 2. If much wording is desired, the best plan is to send the cards to a letterpress printer.

**THE SITTER'S RIGHTS.**—If an operator exhibited specimens (that were taken while he was employed in a studio), in his own studio, would he or his late employer (by whose permission he had the specimens) be liable to be proceeded against by any sitter, or could the sitter only object to them being exhibited?—OPERATOR.

The photographer who took the portraits to the sitter's order

would no doubt be liable for allowing the operator to make use of the portraits, and the operator also would be restrained from exhibiting the portraits. The sitter has the sole right to dictate as to the use of the negative. You should look up the law of the question in the article on "Copyright" in the "Almanac" for 1906.

**ADUROL.**—It appears from the "Almanac" that there are two forms of adurol, the monochlor and monobrom of quinol respectively. 1. Can you tell me whether there is any difference in developments with these two, and which is to be preferred? 2. Adurol is advertised by Hauff and by Schering, but they do not say which kind they offer. Can you say?—C. E. F. M.

1. No marked difference in our experience. 2. Hauff's is the chlorine compound; Schering's the bromine.

**H. F. (Lancaster).**—"Photographic Lenses," by Beck and Andrews, 1s.; "The Watkins Manual," 1s. Both from any dealer.

**A. B. C.**—Better submit best prints. Choose them to illustrate particular districts. Unless they are of a very special character 7s. 6d. to 10s. 6d. each is all you will get for the negatives.

**YTHOMIT.**—We presume you want to reduce the light further, and for this purpose you had better use a calico or other white blind of heavier substance.

**DAMAGED APPARATUS.**—I should value your opinion on the following. I had just finished photographing group of home football team in front of their goal, and before I could get away (scarcely two minutes had elapsed and the game was not starting) one member of the visiting team was practising, kicking the ball against my tripod, 12 x 10 camera, breaking it. I spoke to the individual and to the secretary, and made a claim of 6s. 6d. for repairs. The secretary wrote yesterday declining to compensate me, saying they were not responsible for action of any of their members. Do you think I have a legal claim against the club or its member?—A CONSTANT READER.

We do not see how you can hold the Club responsible, seeing the damage was done by one of the visiting team. Your claim, we should say, must be made against that individual. You do not, however, say if you were employed by the Club to take the photograph, or whether you were permitted by it to take the picture on your own account. If the former, it might be ruled that the Club should give you proper protection while doing the work.

**N. M., Glasgow.**—We can trace no such lecture. Tannin for what? And are you right in quoting "Ratten"? Your query is too vague for us to answer.

**E. ORELING.**—We have no recollection of the formula as you describe it. You will find hydroquinone formula on page 1054 of the "Almanac" (as given for black tones), as good as any you can use.

**GREEN TONES.**—Some time ago I saw some very nice specimens in a pretty green shade. Can you please tell me what paper they would be done on, and where I could get it? They were matt surface prints, very much like a bromide, but of a pretty light-green colour; but perhaps this was obtained by some special bath. 2. I have two portrait lamps, with four incandescent burners on each. I have tried one each side of sitter, so that there is no shadow, but find I get the face so dreadfully hard and no detail whatever in the dress. Can you tell me the reason? I have tried lamps at various distances from the sitter, and find result much the same, except at a long way from the sitter I get negative more under-exposed. I give about 12 seconds' exposure. The faces are always well exposed, and come up very chalky, and eyes so staring, that I have not had any good results. I have found lamp useful on a dull day for relieving. I have been able to get good ones, whereas I could not have taken at all.—D. G.

1. No doubt the carbon process was used. You can obtain the tissue from several makers. See our advertisement pages. 2. If lights of equal power be placed on either side of the sitter, it is not at all surprising that there are no shadows, and that the face is hard and flat, and the drapery lacking in detail. Imitate the effect of daylight as much as possible by having, say, six burners on one side and two on the other. Or by having both

lights arranged on one side—one a little more forward than the others—and softening the shadows by reflectors.

**H. FLACK.**—You are at liberty to start as a dealer without qualifications other than such as will satisfy the trade that you are a bona-fide vendor of apparatus and materials.

**TONING BROMIDES.**—I have been trying to bleach some bromides, for the purpose of toning them, with W. Somerville's formula: potass. ferricyanide, 10 grs.; potass. bromide, 10 grs.; water, 1 ounce. I had the formula made up twice by a chemist, once with ferri, and once with ferro. I have since made it up myself with ferri, and cannot get it to bleach either bromide prints or negatives. The bromides were done about two months ago on Kodak platino-matte, developed with amidol, and fixed in acid hypo (Velox formula). The negatives were developed with pyro-soda, and fixed in plain hypo. As I am a professional and flatter myself a clean and careful worker, I cannot understand why the bleaching would not work. I immersed the dry print in the solution and left it overnight without effect. I have seen the process worked, and want to show my employer the effect produced, and should be glad if you can explain any possible reason of non-success. I have varied the proportions of ingredients to Wellington and Ward's formula, but no result. BROMPTON.

We are quite unable to give any explanation of the non-bleaching action. Occasionally, we have noticed that an image will not completely bleach, but remain a light brown, but this seems to have no ill-effect on the final result. If our correspondent will forward us a print, we will try and bleach it for him.

**ENLARGING DIRECT.**—Can you inform me if there is any process to enable an enlargement to be made on bromide paper direct from a photographic print, without in the first place making negative? If so, will you kindly say where I can get the necessary information?—J. H. BOWHILL.

It would be possible by means of an enlarging camera to project an image of the print on to bromide paper, but obviously the result would be a negative. This could be developed and well washed, and the image converted by means of chromic acid into silver chromate; then the previously unaffected bromide of silver could be developed, and a positive would be thus obtained. It would be possible also to develop the enlargement with eikonogen plus thiocarbamide, and obtain a positive direct. Neither process is practical, and it would be better to make a negative.

**RETOUCHING.**—V. M. M.—The quality of your retouching is second-class only, and the time taken over each example is much too long for the finish given. First-class retouchers would be twice as quick—also placing on the very best work. Your method must be defective. You merely smooth up, and little or no attempt is made to improve the modelling—in fact, you remove it, as instance the wrinkles in the old man's brow, and the line from nostril to mouth. Under careful supervision you would soon surmount these difficulties, and get greater variety into your touch—variety suitable to the different ages of the specimens you forward.

\*.\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The exhibition of colour photography at these offices finally closes tomorrow, Saturday, at 12.30.

The annual meeting of the P.P.A. took place on Friday last, when Mr. Martin Jacolette was elected President in succession to Mr. T. C. Turner. An addendum to the scheme of assistants' certificates was advanced to provide for the large class of "general" assistants. (P. 209.)

"Free sittings" and "free portrait" swindles were the subjects of long comment by Mr. T. C. Turner in his address as retiring President of the Association. (P. 205.)

Half-day closing of photographic establishments once a week. H. Midwinter reports that leading photographers in West Brisbane have resolved on closing at two on Saturdays. A member of the P.P.A. repudiates the suggestion that the practice will be loss to photographers. (P. 218.)

The formation of a colour photography society is suggested. (P. 219.)

One of the oldest pioneers in photography has died in the person of F. Maxwell Lyte. (P. 206.)

Some suggestions are made on obtaining uniformity in the commercial production of portrait negatives. (P. 203.)

The Professional Photographers' Society of New York has planned exhibition by its members, each of whom is to contribute one print bringing the price at which such work might be produced per dozen. (P. 210.)

A new printing paper of the self-toning class was demonstrated by Ernest Morgan in London last week simultaneously with its appearance on the market. (PP. 207 and 215.)

Hereford is named as the meeting-place of the Photographic Convention next year. (P. 216.)

## EX CATHEDRA.

### The Non-Return of Specimens.

Complaints continuing to reach us of the non-return of specimens to those applying to persons or firms whose names appear under a box No., our publishers desire us to make an announcement which we hope will apply an effectual check to this abuse of our advertisement pages. Advertisements asking for specimens must give the full name and address of the advertiser, and those replying to announcements of either class must take the sole responsibility for the safe return of their specimens. In future we will not insert under a box number advertisements asking for specimens to accompany the statement of an applicant's qualifications; and we reserve the right to delete such request from advertisements to appear under a box number. This rule, we believe, will relieve assistants of any cause for complaint, and will defeat the aim of advertisers who, under a cloak of anonymity, obtain specimens which they have no intention of returning. Non-return of specimens, we believe, is due, in most cases, to gross and inexcusable carelessness. On the other hand, we do not hold the applicant entirely innocent in the matter. By his omission to enclose a stamped and addressed wrapper and to mark distinctly each of his specimens with his name, he is not infrequently the sole cause of the injustice of which he so loudly complains. If assistants generally will observe the above conditions, and if they will co-operate with our publishers in refusing to send specimens to a box number, instances of retention of specimens will be things of the past.

\* \* \*

### A "Single-Picture" Exhibition.

The Professional Photographers' Society of New York, which is an organisation alike in aims and objects to the Professional Photographers' Association in this country, is projecting a novel exhibition, to be opened on the occasion of its annual meeting in April. Each member is to send one picture only, and that one made within the year. He is asked to make, mount, and deliver such a picture as he would wish, and could afford, to offer his customers for five, eight, ten, twenty, or thirty, dollars per dozen. There is to be no competition. The members are to foregather and compare notes on what each regards as a production with a certain amount of individuality in it. We shall be curious to hear how the proposal is taken up by the members. The idea is one which should certainly accord with the American's willingness to talk shop with the brethren of his craft, and the exhibition can hardly fail, it seems to us, in raising the standard of photographers' work and of helping the average small man to move with the times.

### The Art Training of Photographers.

Mr. J. C. Dollman, in his lecture at the Society of Arts last week, which we propose reprinting in our next issue, suggested that a course of art training would be very desirable for photographers who have artistic aspirations, and few will disagree with him. Even a very little knowledge of first principles would save us from much that passes for art in the photographic world, though it would not so pass in the world of true art. It would be a great gain if photographers knew how to respect and make use of the limitations of their craft. At present they far too often treat them as awkward fences that must be rushed and got over at all hazards, and the result is that they are left sitting on these fences, unwilling to climb down the way they got up, and quite unable to descend the other side. It would also be a gain if they learnt the paramount importance in all art crafts of using the capabilities of their materials to the best advantage. Two great capabilities of photography are its unique power of delineation and its extreme delicacy in the representation of detail and gradation. If painters only possessed such powers, they would know how to use them, and would certainly not neglect them. The photographer has both at his command, but too often despises both equally, and the trouble that he will take to eliminate them would greatly astonish a real artist, if he were to be let in behind the scenes. A little true knowledge of art would also enable the photographer to place a right interpretation on various terms that have well defined meanings in the art world, but so often degenerate into cant phrases and catchwords in the mouth of the would-be artist. For instance, he would learn that "the power of creation" (a term much used by Mr. Dollman in his paper) does not imply the power of making something out of nothing. Also that "breadth" does not mean the diminution of definite purposeful detail and the substitution of indefinite meaningless confusion. Breadth is the very opposite of confusion, and it is not even added to by scratching over the surface of the print, though some few photographers seem to think it is. After a few years' study the photographer might also arrive at the important truth that "impressionism," properly so-called, is not within the scope or capabilities of photography. All the photographer can do in this direction is to produce bad imitations of what Mr. Dollman called "beginnings of pictures," executed by those described by Mr. David Murray, R.A., as "impressionists because they could be nothing more."

\* \* \*

### A Life School for Photographers.

Mr. Dollman's suggestion of a course of general art training for photographers would be especially difficult to carry out, in view of the fact that the average photographer so quickly masters his tools, and so quickly begins to turn out "exhibition pictures," and so soon finds an entry into the semi-art world of photographers, that it is difficult to convince him that he is in need of any general art training at all. He is already a maker of pictures, and, therefore, in his own estimation, is better qualified to be a teacher than a student. Mr. Dollman, however, made the very definite suggestion of a life school for photographers, and it appears to us that such a school established for such a purpose would not only be of undoubted value, but might easily be very successful. We agree with Mr. Dollman that "the greatest things that photography is going to do in the future will be associated with the figure,"—in fact, we think that this statement has a past and present application as well as a future one, and it is, at any rate, evident that the great majority of photographers depend for a liveli-

hood upon figure work and that alone. A well supervised and definite course of study in a life school would be of the utmost value to the young professional, whose ideas of the possibilities of figure work in the studio are often so limited that he degenerates into a one-pose man, with no interest in his work excepting so far as it influences his banking account.

### The Photographic Exhibition in Paris.

On another page of this issue we publish a letter from M. Gastine addressed to the editor of the "Photographic Monthly," by whom it has been handed to us with permission to publish it. We suppose we may assume that M. Gastine, who complains of the hostile attitude of certain of the photographic Press in this country, has no objection to our making use of his communication, although he does not address it to us. His account of the opposition of the "Chambres Syndicate" to the proposed exhibition is that these four bodies are insignificant, and are in fear of British manufacturers making a prominent show at the exhibition. The aim of the "Chambres," we may infer from M. Gastine's remarks, is to throw cold water on the exhibition, and so create the impression that the enterprise cannot be brought to a successful issue. Although this official action has been taken, individual members of these bodies, we are informed, will exhibit, notably the firm of Lumière. Yet it is no disparagement to the great Lyons firm to say that one swallow does not make a summer, and we should wish to know that a like support is forthcoming from the French photographic trade. As for M. Gastine's view that the Photo-Club and its active members, MM. Demachy, Puyo, Bucquet, and others representative of pictorial photography in France are directed by a small section of the syndicates, it may be dismissed as preposterous. We are not so well informed of the Société Française de Photographie, but we are pretty certain that any member of it would repudiate such an allegation in regard to the Société.

\* \* \*

### Requirements in Local View Work.

The remark that the local view business has been killed by the big view publishing houses and the picture postcard craze is often heard nowadays. Yet we think the man on the spot will always find that at least some view work can be done, and that enough to make it worth while. The fact of being on the spot all the year round means that the best views can be selected and taken under the most favourable conditions or under various favourable conditions. Just now the opportunities for view work are very good. During the next few weeks many pictures may be secured in which the trees with the buds or opening leaves will half conceal and half disclose ruins or other buildings in the middle distance. The spring time usually gives a clearer atmosphere for distant views, and where possible these should be taken on orthochromatic plates, using at least a ten times light filter if one of the yellow-green sensitive brands of plate is employed. Those views in which near foliage occurs may need to be left until June possibly, for then the days are frequently stiller, and a windless day is essential if the best results are to be obtained. But even in spring quiet days come occasionally, and should be made the most of. While we thoroughly advocate the production of pretty and artistic views, it should not be forgotten that historic and topographic views find the greater number of purchasers, and a view showing the situation of the principal hotel, or the Constitutional Club, will find purchasers even if it possesses no pictorial quality.

**Lenses for Portraiture.**

The article by M. Leclerc de Pulligny, on "Anachromatic" lenses, which appeared in our issue of March 9, contains some valuable hints on the regulation of the distance between sitter and lens, which hints we specially commend to the notice of those who so frequently ask for information relating to length of studio and focal length of lens. It cannot be too frequently insisted upon that too short a distance between lens and sitter must inevitably produce distorted or apparently wrong perspective, and, therefore, must destroy the fidelity of the "likeness." If a large image is required, lens of long focal length is a necessity, and no other expedient (save enlarging) can be adopted if the photographer has any desire to do justice to his sitter. Mr. C. Dollman, A.R.W.S., in the lecture on "Art in Painting and Photography," which we shall shortly print, emphasises the same point when he states that many photographs that represent natural expression and faithfully record the features fail to be successful likenesses, because the camera has been brought too near the sitter and the perspective is exaggerated. In Messrs. Goerz's recent pamphlet on "The Telephoto Lens" there is an example of the precise effect produced. The effect is intentionally exaggerated for purposes of illustration, as in the one case the distance of the camera is 6 ft. and in the other only 1 in., but the character of the defect is admirably shown.

\* \* \*

**Diffusion Focus.**

A very satisfactory note is struck by Major Puyo and MM. Demachy and Pulligny, when they condemn, "that woolly fuzziness that all real artists detest." The diffusion that they claim to be produced by the anachromatic lenses is of an altogether different nature to the so-called diffusion produced by putting the image out of focus or by resorting to even creditable expedients. It will be noticed from the details given that sharp focus is secured with the anachromatic lenses on the violet image so that the result gives the impression of sharpness. The illustrations show that the impression of sharpness is well preserved in the prominent high-lights and adjacent shadows, while the half-tones and least important shades and shadows are softened by diffusion. The effect is very different from that produced by throwing the important details and the less important all out of focus together. The one gives "breadth," the other destroys it, though too many photographers wrongly imagine that "breadth" is gained by the destruction of focus. It will be seen from Major Puyo's paper that the degree of sharpness attained is largely under control by varying aperture and exposure. It would appear that it must also be affected by the colour sensitiveness of the plate, but this he does not mention. A point of interest is the behaviour of these lenses when used with orthochromatic plates and properly adjusted colour filters. Upon this we have no information, but true values of such importance in artistic work that information is desirable.

\* \* \*

**Substitute for Platinum.**

According to the "English Mechanic," an American claims to have discovered a substitute for platinum, which, it is said, can be manufactured in large quantities in a very short time. The new metal is greyish-white, with a specific gravity and atomic weight about the same as platinum. It melts at about 3,630 deg. F., and is malleable and ductile, and can be rolled into sheets, drawn into wire, and is not attacked by acids. A correspondent to the same journal states that he has discovered something of the same in a deposit in Jersey. If all these statements are true, we may yet have another metal added to those which are at present utilised for photographic printing processes.

**The Exhibition of Colour Photography.**

The suggestion made by Mr. Howard Farmer last week in our columns that the exhibition of colour photography which closes to-morrow should be preserved intact as far as possible has been very favourably received by a number of the exhibitors. At the time of writing, those who signified their willingness for their work to be transferred to a permanent collection are:—Miss S. A. Acland, F.R.P.S., Fuerst Bros., H. O. Klein, E. R. Grills, The Autotype Co., Otto Pfenninger, Leon Vidal, Dr. Albert Norman, Edwin P. Butler, and Captain Lascelles-Davidson. In one or two instances the actual examples in the exhibition are not available, but would be replaced by others. As to the home of the collection, several suggestions have been made, but we will wait until other exhibitors have had time to communicate their views before referring further to the proposal.

\* \* \*

**Methods of Getting Soft Enlargements.**

One of the advantages of enlarging by daylight is that the stronger type of negative, which is largely used for such processes as matt, collodio, chloride, and carbon, will give soft results. Using such illuminants as oil or incandescent gas, the more opaque portions of the negative are not penetrated by the light before the shadows are fully exposed, and hence hard pictures result. Daylight, too, is less apt to emphasise the small defects in film, varnish, or glass, owing to its diffused character. Softness of contrast may be secured with artificial light by the use of a rapid bromide paper and dilute rodinal, say, 1-100, as a developer, development being stopped when the shadows are sufficiently strong by transmitted light. By enlarging on a rough-surfaced paper, softer effects are obtained, the shadows being broken up somewhat, and a cream-tinted paper still further softens the result. When a bromide is toned to a sepia colour by the well-known method of iodine bleaching and subsequent sulphiding, the contrasts are not only softer, but the variation of colour is pleasing. Still further modifications may be obtained by the employment of bolting silk, though this should be done with caution on account of the softened definition which is not always acceptable.

**THE PRINTING QUALITY OF NEGATIVES.**

One of the most important points in professional photography is uniformity of results, and we think most workers of experience will agree with us when we say that if uniform negatives are produced more than half the difficulty is overcome. It may be taken for granted that the commonest variations are variations in printing strength or range of gradation—that is, negatives are made too strong or too weak for the process for which they are intended. That a negative shall have shadow detail, or, in other words, that the gradation shall commence with the recording of the darkest tones of the subject, is practically essential for every process, and is usually attained by any worker with a little experience. Sufficient exposure ensures this quality. The various steps in the scale of gradation must also be recorded, and this is to some extent a matter of correct exposure, but more a matter of excellence in the quality of the emulsion and liberality in the coating of the plate. The range of gradation, or difference between the light stopping power of the shadows and of the high lights, is affected by several factors, but mostly by the duration of development. The "density" is usually estimated by the worker by transmitted light from the dark-room lamp, and it is in this exercise of judgment that the errors arise. If we can eliminate judgment, which is always liable to error, and work more or less mechanically, uniformity of result is more probable. Of all the points in photographic practice there are few more difficult than

the estimation of density during development and the decision as to the correctness of the range or printing quality in the finished negative. If we could but ensure absolutely uniform conditions our plates might be developed for a uniform time, and uniform results would be obtained. Is it, then, easier to allow for the variation in certain factors, which, as we shall see presently, affect the range of gradation in our negatives, or to adhere to the old method of stopping development when, after a visual examination by transmitted light, we judge that sufficient density has been obtained?

We need hardly argue the value of uniformity in professional work. The amateur is often advised to try his negatives in various printing processes until he hits upon the most satisfactory result. This is another way of saying that the amateur is often unable to produce a definite type of negative at will. Obviously the professional who takes his order for carbon or platinotype must produce his prints in carbon or platinotype, and his negatives must be made of a character suited to the selected process. How may this be done with the greatest ease and certainty?

Let us first of all consider what are the causes of variation in the range of gradation or printing quality of negatives, and to avoid complication let me consider the matter solely from the standpoint of portrait work in the studio. Variations in range of gradation may be produced by:—

1. The contrast in the subject.
2. The brand of plate used.
3. The exposure—i.e., so-called over or under exposure.
4. The constitution of the developer.
5. The temperature of the developer.
6. The duration of development.

Taking the six points enumerated and examining each separately and from an every-day practical point of view, we may arrive at certain conclusions.

1. The contrast in a portrait subject is largely under the photographer's control. An exceptionally strong light can be softened in the usual way by means of a diffuser, and the contrast may be still further reduced by means of reflected light. When the light is very weak and poor, however, the contrast in the subject may be too slight, and in such cases steps must be taken to *increase* the range of the negative. Over-exposure must be carefully avoided, and development slightly prolonged. Negatives taken under such conditions are frequently intensified, a process always to be avoided, if possible.

2. The brand of plate used may be always kept to, and its characteristics and density-giving power become known. Any variations under this head would only arise from differences in various batches of emulsion, and would be so slight as to be negligible.

3. If work is being constantly done under ordinary studio conditions exposure should furnish few difficulties, for the latitude of modern plates is such that half or double the normal or "correct" exposure may be given without the range of the negative being practically affected. As a rough guide to exposure it will be found that one second may be given for every minute a Watkins meter takes to darken to the light tint. The meter is placed in the position the sitter will occupy, the stop in the lens being  $f/6$ , and the plate of a speed of 200 H. and D. The subject is assumed to be an inch and a half head and shoulders portrait.

4. The constitution of the developer must be kept constant. Stock solutions should be made up by careful measure, and not by guess-work, and the working solutions must also be measured each time. An important point to be observed is that sufficient sulphite of soda must be included to prevent any stain, even in those cases where unavoidable variations of other factors render it necessary to prolong

development. As Mr. Chapman Jones has frequently pointed out, nothing is so uncertain in its effect upon the printing range as stain, which, it is safe to say, cannot be produced in uniform degree. It must not be forgotten that at summer temperatures a solution of sodium sulphite will deteriorate in as short a time as twenty-four hours, absorbing oxygen from the atmosphere and becoming sodium sulphate, when stain-preventing power is lost.

5. When we come to the question of the temperature of the developer we touch the weakest spot in the system we are advocating. Although the variations of temperature in England are much slighter than in America or on the Continent, it is highly probable that the actual temperature in dark-rooms varies more here than anywhere else. Where both heat and cold are greater, steps must perforce be taken to produce comfortable working conditions, but in England the proportion of really cold or very hot days is small, and so no adequate provision is made for them. Under any method of working, however, a low or a high temperature in the developing room brings its attendant evils. The dark-room should be so situated as to be not unduly exposed to the outside air or to the direct rays of the sun, and by some method or other it should be warmed in winter to a temperature of 60 deg. Fah., and kept cool during the summer by proper ventilation. By hanging up a thermometer in the room the variation from the normal temperature—and 55 deg. or 60 deg. may be regarded as such—can be noted, and, as Mr. Chapman Jones suggested in his Traill-Taylor lecture, allowance may be made accordingly in the length of development. One or two experiments will readily show what percentage of increase must be given when the thermometer falls 5 deg., and what percentage of decrease when it rises an equal amount. Some developers are more affected by variations of temperature than others, hydroquinone being almost inert at low temperatures.

6. The duration of development is well understood to be the principal factor affecting range—the longer the time of development the greater the range. If, however, fog occurs, either through stray light, unsafe illumination in the dark-room, or an unsuitable developer, the fog may develop to such an extent as to cause a diminution of range with prolongation of development. Also, if the plate has been over-exposed, and potassium bromide added to the developer to counteract this over-exposure, the darker tones will only be held back during the early stages of development, and the printing range may be lessened by carrying development beyond a certain point. That point will vary according to the degree of over-exposure.

To summarise, we see that the plate and the constitution of the developer are two factors out of the six which may be kept constant. Where the contrast in the subject was very slight the plates would be placed in a separate box for development for an increased length of time—say 25 per cent. longer. With this occasional exception the contrast in the subject is also a constant. Experience enables a reasonably correct exposure to be given, and by taking ordinary precautions we have seen that the temperature of the developer need not vary to any extent during the greater part of the year. It will thus be seen that exposed plates may be developed for certain lengths of time, and that negatives suitable for the various printing processes can be obtained with more certainty than by the old method of estimating density. The range of gradation for any particular process varies with the make of paper employed or with the strength of the sensitising bath, and the personal equation also comes in, for some workers prefer a rather stronger negative for a process than others. The following rough figures, however, will suffice to indicate what may be done. Four plates, all exposed with approximate correctness, were developed in the same developer

per for six minutes, eight, twelve, and sixteen minutes respectively, and the resultant negatives were suitable for printing in P.O.P. or bromide, platinotype, black carbon, and red chalk carbon respectively.

We have been led to give more detailed consideration to this subject because we have quite recently had several

cases brought to our notice where workers seemed unable in the ordinary way to get negatives which gave them the character of print their clients and they themselves desired. The method we have advocated is practically that in use in the developing machines which have been so successful during the past few years.

## “ INVITATION SITTINGS ” AND “ FREE PORTRAIT ” SWINDLES.

In the course of a brief review of the year's work, the retiring President of the Professional Photographers' Association (Mr. T. C. Turner), at the annual meeting held on Friday last, emphasised the two dangers—one internal and the other external—to which professional photography was exposed. The substance of his address is given below.

It affords me very great pleasure to perform the duty which devolves upon every president, of submitting a few observations with reference to the progress of our Association; but I could not allow myself to proceed without first offering to Mr. Ellis my personal thanks for his kindness in presiding over many of the meetings in London. When, gentlemen, you were good enough to elect me to the honourable position, I was obliged to regard it chiefly as a compliment to my provincial brethren, knowing that my professional duties in Yorkshire could prevent me from being with you as often as I desired. I need, however, hardly say to those of you who have enjoyed the privilege of Mr. Ellis's direction that the Association has lost nothing by these deputed duties.

In glancing over the annual meeting reports of various trade and professional associations, one is often struck by a certain similarity of experience. Members forget to pay their subscriptions, and fall away from the body at whose birth they so enthusiastically rejoiced.

Well, in a measure, perhaps, our Association also suffers from the effects of reaction, and especially when, owing to the difficulties of meeting together, we miss the cheering, supporting influence of large gatherings. But, in spite of this, I have never met a photographer who regards as vain the work which has been done during the past four years by the committee in London and by the branches in the provinces.

It seems to me that, divergent as our view may be as to the method of advancing *individual* professional interests, we are all agreed that the aims of the Association are healthy and altruistic. It is in this spirit we have approached the vital question of the “ invitation sitting.” No one supposes for a moment that any rules of business conduct could be framed, or if framed, would gain the loyal support of all our members, unless they are convinced that wisdom lies that way, that common sense demands mutual protection, and perhaps individual self-sacrifice. Our efforts must therefore remain largely of a missionary character, and be directed towards the formation of a certain professional tone or opinion which is in itself the best protection against unprofessional conduct. I believe that this alone will retrieve that position of public appreciation which has in certain directions become endangered by the conduct of photographers working on ultra-commercial lines.

As “ tradesmen ” we shall never be able to excel in our work, and daily contact with the little meannesses of the invitation system is surely calculated to cramp, if not destroy the power to produce portraiture of high excellence and lasting credit to ourselves. It is only by living, and thinking, and working as a professional class of men we can hope to stem the current of vulgar mediocrity which threatens to swamp all that is best worth striving for in modern photography as a calling.

If this danger arises from within, we have to face another, perhaps even more destructive, from without. The various free portrait swindles that are being worked all over the country are doing an immense amount of harm. The persistency and ‘cuteness’ which is brought to bear upon large sections of the public by wholesale canvassing directed by unscrupulous men is worthier of a better object than the degradation of photographic portraiture and the impoverishment of men who are prepared to give honest value and have an established reputation to consider. Yet we have to face stubborn facts, and our Association is doing its best to assist its members by bringing to them all the information obtainable to enable them to protect themselves against a form of competition as unfair as it is detrimental to the public interests at large. I could instance one firm which had a turnover of £5,000 in six months, and employed some forty or fifty people in canvassing at about £2 or £3 a week. The artist received 4½d. for working up the enlargement, which fetched as much as 40s. or 50s. It was no less than a gigantic swindle.

We are all accustomed to hear that the time has arrived when there is no middle path to success left in photography. A man must either produce portraiture of such high quality that it will appeal to the cultured, discerning few, or he must descend to the level of the mob, and become little better than an automatic photographic machine.

A certain commercial success always attends unskilled work if it is cheap enough, and this appears to have encouraged such an army of penny photographers that instead of the sign of a public-house being the commonest object in our cities, that of the “ sticky back ” man predominates.

But “ photography as a profession ” is a thing impossible on any such lines, and as the chief object of our Association is to raise the status of its members, our best efforts might well be directed to the encouragement of highly trained portraitists. The Professional Photographers' Society of New York, the P.P.A. of America, has conceived the happy idea of forming an exhibition under its auspices of professional work. Members are invited to contribute one portrait each, and the price obtained for it is also stated. Such an exhibition here would assist photographers to form an opinion of the general valuation of good work, and also act as a tonic against the enervating ideas that good professional photography commands comparatively little attention.

The proprietors of THE BRITISH JOURNAL OF PHOTOGRAPHY have rendered an excellent service to the professional by their exhibition of colour effects in photography at Wellington Street, and our friend Mr. Brown, the Editor, has made a suggestion to me for an exhibition of professional photography on somewhat original lines, which our committee are now considering.

T. C. TURNER.

## THE LATE F. MAXWELL LYTE.

ONE of the last links which bind photography of to-day with that of fifty years ago is severed in the death, on March 4th, of Mr. Farnham Maxwell Lyte, at the great age of 78. The name of the deceased gentleman is unknown no doubt to many who are now in middle life, for Mr. Maxwell Lyte's connection with photography was not a lengthy one—it lasted only some sixteen years, and it concluded almost exactly forty years ago. Yet the journals in the fifties and sixties show him to have been an exceedingly active experimenter, and present day photographers have reason to remember him, chiefly perhaps as the originator of the borax and phosphate toning baths. His most notable achievement in photographic progress was, however, the invention of the so-called "honey" process, by which the wet collodion plate could be retained in workable condition for several days. This process he published in "Notes and Queries" for June 17, 1854, his letter appearing a fortnight after George Shadbolt, a former editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*, had independently communicated an identical process to The Photographic Society (now the Royal Photographic Society). Mr. Lyte was a chemist by profession, and applied his chemical knowledge to many diverse photographic problems of his day. Thus he was one of the first to point out the danger to photographs of "antichlor" impurities in mounts. He was an honorary member of the Royal Photographic Society.

Some time ago events brought us into communication with Mr. Lyte, whose interest in photography had not diminished by his long enforced abstinence from practical work. At our request he then penned some notes on his photographic career, some portions of which we may fittingly quote, as throwing a vivid light upon the practice of the art in his early days.

\* \* \* \* \*

As I write these notes, entirely from memory, I greatly fear I may be mistaken as to the correct dates. I first began to take an interest in photography about the year 1844, when I was sixteen years of age, being attracted thereto by a printed leaflet kindly sent me by Mr. Fox Talbot, through a lady, a relation of his, and a cousin of my mother's. It was not, however, till after 1851, when I had finished my university course, that I at all seriously took up the subject. During 1852 and 1853 I had a good deal of correspondence in the pages of "Notes and Queries" on the subject. In the autumn of 1851 Scott Archer's great invention of the collodion process came out, and I soon began to put it in practice. I remember well the interest it then excited, and some Grand Duchesses, members of the Russian Imperial Family, at that time resident at Torquay, whither I had been ordered on account of some delicacy of the chest, took the keenest interest in it. They seemed to look on photography as a mysterious art, almost allied to witchcraft, and they then became patronesses of a lecture I was induced to deliver on the matter. It was in 1854, as far as I can remember, that I sent a few of my productions to an exhibition got up by Delamotte, of Bond Street. These greatly interested H.R.H. the Prince Consort, who desired his secretary to inquire if I would sell them. I replied that I was too much flattered, and hoped he would do me the honour of accepting them.

### The Honey Process.

Photographs taken at this time are now much faded, the alkaline toning, which I invented during the sixties,\* and which I think is published in the *JOURNAL*, not having then been invented. Soon after being sent abroad, I invented the "honey" process, which was, I believe, the first successful attempt that had then been made at preserving the collodion plate in a state of sensibility for some hours. I did many pictures by its means during my residence at Pau, and afterwards on my return to England, when I had the honour of explaining and demonstrating it to H.R.H. the Prince Consort, in his little photographic workshop in the garden at Buckingham Palace. Some of the photographs done at Pau by this process were among those exhibited in the Paris Exhibition of 1855. H.R.H. the Prince Consort had also the Paris collection sent to him by his desire.

\* An alkaline toning bath was in use several years prior to Maxwell Lyte's first advocacy of it.—Eds. B.J.P.

I found later on that the honey process was not to be depended on. Not all samples of honey will bear the addition of nitrate of silver, which seems essential to the great increase of sensitiveness, one of the chief merits of the process, and the tacky nature of the honey causes the adherence of particles of dust, almost unavoidable, producing comets and blotches of all kinds, so that at last I abandoned the process altogether.

When I see on all sides the beautiful instantaneous dry plate work now being produced I feel quite ashamed of obtruding on any one any allusion to my feeble attempts of years ago. It is only as a record of what was done by one of the first pioneers of collodion photography that what I here write can possess any interest. If I have succeeded at that early period better than some others, it is in great part attributable to my having myself prepared or purified most of the chemicals I employed, and the care I took to ensure their purity. My ether and alcohol I always rectified over caustic alkali; my pyroxyline I made for myself generally from cigarette paper, which, being unsized, thin, and made from the purest linen rags, (no filling in) became more thoroughly pyroxylinised throughout, and gave a more homogeneous product than even cotton, which requires frequent agitation. Everyone is in love with his own crotchet, but I thought it gave me a solution in the alcoholised ether, which flowed more easily, gave a tougher film, and left less insoluble matter than all other samples of pyroxyline. I even found it economical to make my own nitrate of silver. I well remember being soundly rated by an old French viscount for my waste and extravagance in dissolving a lot of five franc pieces in nitric acid. However, it was at that time the cheapest means of getting nitrate of silver out there, and by taking care only, as far as possible, to use pieces which had been coined before a certain date, I recovered enough gold to tone all the prints made with the nitrate of silver produced.

### Iodized Collodion.

As soon as Scott Archer's invention of the collodion process was published, I was not long in perceiving the advantage that would accrue, especially to the better delineation of the greens in landscape photography by using an admixture of bromides with the iodides Scott Archer had recommended. My attention had been drawn to the superior sensitiveness of the silver bromide to green rays, as compared with the iodide specified by Scott Archer, by Mr., now Sir, William Crookes. The iodising formula I finally settled on, which, I believe, is given in the *JOURNAL*, was composed of iodide of ammonium with bromide of cadmium, and gave a collodion, which kept well for a long time after mixing, if only prepared with freshly rectified ether and kept in well-filled bottles, was fairly sensitive, and gave good definition in the greens.

In landscape work in the Pyrenees, where all my photographs were done, the direction of nearly all the valleys is north and south, with but few side valleys. The consequence is, that, to avoid having the sun's rays striking direct into the lens, most photographic work, in order to be successful, requires to be done either in the early morning or in the afternoon. It is, however, at these times of the day that the lights and shadows become most clearly marked, and that the different planes of the distance are most clearly defined, so that it can hardly be said to be a disadvantage.

I always use inside my camera, at the back of the lens, a rectangular diaphragm, of the same shape as my dark frame, this diaphragm being adjusted such a distance from the lens as to cut off all the lateral rays that would strike the sides of the camera without interfering with the luminosity of the image. These lateral rays may at times produce fogging. This arrangement I found especially useful in dealing with a strong front light, but probably it is seldom entirely without effect, and to it I attribute the great clearness of some of my photographs. Its usefulness becomes particularly apparent when one takes two photographs, one with the diaphragm, the other without it.

In one of the early numbers of the *JOURNAL* I prescribed the use of formic acid as a substitute for acetic acid in the developer. It was then a very costly product, but lately a process has been brought

for its manufacture at a price which puts it within the reach of photographers. It has some properties which recommend it. Formic acid and some of its salts are almost developing agents in themselves.

F. MAXWELL LYTE.

August 13th, 1903.

Mr. Lyte was a chemical engineer and an Associate of the Institution of Civil Engineers. He was one of the oldest members of the Chemical Society, and an original member of the Society of Chemical Industry. His father, the Rev. Henry Francis Lyte, may be remembered as the author of the well-known hymn, "Abide With Me."

## A NEW SELF-TONING PAPER.

(A lecture delivered by Mr. Ernest Morgan before the Cricklewood Photographic Society, on March 7.)

PRINTING-OUT papers are the mainstay of the photographic printer the world over, and although there are several other excellent methods of printing from the photographic negative, the great majority of prints made by photographers, from the school-boy with his first five-shilling camera to the professional photographer who makes his life in making photographs, are made, upon a printing-out paper either as gelatino-chloride or collodio-chloride. Any modification or improvement therefore in a process of such wide and general use must be of the greatest interest and importance to everyone practising photography.

The qualities which have secured for printing-out papers the popularity they enjoy are firstly the very beautiful quality of print obtainable upon them which combines a very delicate rendering of the details of the photographic negative with extremely rich and transient shadows, the beautiful purple brown colour of the well-toned print, and the great simplicity of the process. With every other method of photographic printing it is necessary to ascertain the length of the exposure the paper requires to fully print the detail of the negative either by trial or by the exercise of trained judgment and experience, but printing-out papers print with a visible image so that the progress of the printing may be observed and the amount of exposure given with the greatest accuracy, and it is no doubt to this quality that the process owes its universal popularity.

Considering the importance of this process of printing to the photographer it seems very remarkable that so little improvement has been made in the manufacture of such papers since the process first came into use. From the time when Fox Talbot, more than fifty years ago, coated paper with chlorided albumen, and sensitized the coated paper on a nitrate of silver bath, there has practically been no improvement made in the quality of the print, and very little in the simplification of the process, although during this period we have had great and continuous improvements in the methods of making the photographic negative. We have seen in this department of photography the wet-plate give way to the dry plate, marking an immense step in the simplification of the process of producing the photographic negative, and there has been steady and continuous improvements in the manufacture of the apparatus used, the camera and lens, and the production of new and improved developing agents. Beyond the substitution of collodion and of gelatine for the albumen vehicle first used, the history of silver printing has little to record. I hope to show you this evening that an important simplification of the process is now possible, and has been achieved by the production of the "Richmond" paper.

Now I claim for the paper that the tone, which is a rich purple-brown, resembling a fully-toned collodio-chloride or gelatino-chloride print, is actually obtained by the toning action of the gold, and by the reduction of the gold contained in the paper only.

### Self-Toning in an Alkaline Bath.

You will see by the instructions issued with the Richmond paper that the only conditions necessary for a completely finished print upon it are that it should be washed for not less than 5 minutes in running water, and should be fixed for from 10 to 20 minutes according to the tone required in a hyposulphite of soda bath of the usual strength, 1 to 3 ozs. of hyposulphite of soda dissolved in 20 ozs. of water. You will also see we recommend, in addition, that this fixing bath should be rendered decidedly alkaline by the addition of a small teaspoonful of bicarbonate of soda, or, more accurately, one drachm by weight. The addition of the soda prevents any possibility of the bath

being decomposed by any little acid which may remain in the coating of the paper after washing, which might decompose the hyposulphite of soda and cause sulphuration of the image. It is very necessary to guard against this danger, as although the decomposed bath would to some extent tone the print even if no gold was contained in the paper, it is a very dangerous and uncertain method of toning, and generally bleaches the print and yellows and degrades its lights. There is always a considerable amount of free acid in printing-out papers, and unless some precaution of this kind is taken, or prints are washed for some considerable time, there is always danger of sulphur-toning occurring, especially when a number of prints have been passed through the fixing bath, and acid from them has accumulated in the bath. You will notice that we advise that the prints should be washed for five minutes. This is the minimum time, and you may wash them for ten minutes or for half-an-hour if you choose; the paper will still give perfect tones, but photographers generally do not like to take longer for their operations than is necessary, and although five minutes' washing would not be sufficient for a gelatino-chloride print, the vehicle used in the "Richmond" paper, which is neither collodion nor gelatine, is of a porous nature, and can be sufficiently freed from its soluble parts with five minutes' washing.

### Properties of Agar-agar Paper.

And now a word concerning the vehicle used in the "Richmond" paper for carrying the sensitive salts which, as I have already told you, is not either collodion or gelatine, but a new product not hitherto used with success in photographic processes. Very early in the series of experiments in which I have been engaged for some years with the object of producing a satisfactory self-toning paper, I found that gelatine as a vehicle was quite unsuitable, and without going into the technicalities of the manufacture, which I am afraid would not be of general interest, I will content myself by saying that as far as my trials carried me I am quite unable to obtain good tones by toning with the use of a hypo. bath only, when gelatine was employed. There are also many objections to collodion, such as the curling and cracking of the print amongst other reasons, and I was at length successful in finding a totally new medium, which has proved to my greatest satisfaction.

This consists of a combination of agar-agar, a Japanese seaweed (the chief use of which in this country has been as a vehicle used by the chemist as a culture for bacteria), and of boiled starch. You will see by the specimens before you that it gives a very beautiful textureless surface quite pure and colourless in the whites of the picture, and resembling very closely the appearance of collodion. Besides being peculiarly adapted for printing papers containing gold, it has another very considerable advantage in being affected very little by temperature. I believe it is practically impossible to make it blister or frill in any natural temperature, and prints made upon it may even be left in warm water of a temperature of 150 Fahr. without injury. This property renders it an ideal product for use in hot climates, and I have no doubt it can be used in the tropics or the arctic regions with the same success and facility as it can in our more temperate climate. Prints can also be dried off rapidly by heat, the only limit being that the prints should not be scorched, and this property has a very great advantage over gelatine, which is liable to blister even at low temperature, and cannot be dried off rapidly.

The "Richmond" paper will also yield very fine black tones by the use of a very simple supplementary platinum bath. For black

tones the prints should be first soaked for five minutes in a bath of 1 oz. of hydrochloric acid to a pint of water, in order to completely convert the free silver of the paper to chloride, and after rinsing in water may be toned by immersing in a bath containing 2 grains of

chloroplatinite of potash to each 10 ozs. of water. Prints so treated will tone to a fine black colour in about 10 to 15 minutes, and may then be washed and afterwards fixed in the ordinary hypo-sulphite of soda bath.

ERNEST MORGAN.

## FOREIGN NOTES AND NEWS.

### Iron Citrates.

By acting upon citric acid with iron, caustic soda and ammonia, many single and double salts may be formed according to the proportions of the reacting substances. Dr. G. Siboni has prepared a considerable number of these in the *Apothetische Zeitung*, 1905, p. 1018, which we briefly describe in the following summary:—In the formulae here given  $H_3Ci$  stands for citric acid  $CH_3COOH.C.OH.COOH.CH_2COOH$ ,  $H_3$  being the three hydrogen atoms of the carboxyl groups. 1. Ferrous citrate:  $H.Ci.Fe^{II}+H_2O$ , by direct action of Fe upon  $H_3Ci$ ; a pale green crystalline salt not readily soluble in water; forms supersaturated solutions. 2. Ferrous ammonium citrate:  $CiFe^{II}/NH_4$  by solution of No. 1 above in ammonium hydrate; unstable, loses  $NH_3$  at  $120^\circ C.$ , readily oxidises to ferric salt. 3. Ferrous sodium citrate:  $CiFe^{II}/Na$ , by addition of  $NaHO$ , or  $Na_2CO_3$  to No. 1 until neutral. 4. Ferric citrate:  $CiFe^{III}+3H_2O$ , by solution of freshly precipitated ferric hydrate in the acid; though nominally a neutral salt, has an acid reaction, and takes up  $NH_3$  with evolution of heat, resulting compounds being named by the author "ammines." 5. Ferric mono-ammine citrate  $Ci_3Fe.NH_3$ . One kilo. of citric acid is digested with the ferric hydrate obtained from 3 kilos. of ferric chloride solution; after filtration, 207 grams ammonia solution, specific gravity 0.925, are added, the mixture being concentrated and dried on glass plates, forms bright red flakes with acid reaction. 6. Ferric diammine citrate  $Ci_3Fe_2.(NH_3)_4$ , prepared as above but with double the amount of ammonia; also formed by oxidation of No 2 salt. Dark brown, acid, deliquescent. 7. Ferric triammine citrate  $Ci_3Fe_2.(NH_3)_6$  by complete neutralisation of No. 4 with ammonia. The official iron and ammonium citrate of the British, Dutch, Italian, Swiss, and U.S. pharmacopoeias. The German, Russian, Norwegian, Roumanian, and Greek pharmacopoeias prescribe an addition of citric acid to the ferric citrate before neutralising with ammonia. In this way combinations may result of the following constitution:—8. Mono-ammonium ferric citrate,  $H_3Ci_3Fe_2.(NH_4)$ , from 593 grams ferric citrate, and 210 citric acid dissolved in a sufficiency of water, and treated with 85 grams 20 per cent. ammonium hydrate. Yellowish-brown flakes, deliquescent, strongly acid. 9. Diammonium ferric citrate,  $HCl_3Fe_2.(NH_4)_4$ , as above, but twice the amount of ammonia. Greenish-yellow flakes, very deliquescent. 10. Triammonium ferric citrate,  $Ci_3Fe.(NH_4)_3$ , as No. 8, but three times the amount of ammonia. Similar in properties to No. 9. 11. Tetra-ammonium ferric citrate,  $Ci_3Fe_2.(NH_4)_4.(NH_3)$  as No. 8, but with fourfold the quantity of ammonia. Must be evaporated at low temperature otherwise  $NH_3$  is evolved. Corresponds with the German official compound.

### Spots on Prints.

The cause of spots on silver prints is ascribed by Namias to the presence of acids either in the cards or mountant. He suggests that prints should therefore be soaked, after washing, in a 4 or 5 per cent. solution of borax, the excess of solution blotted off, and the print mounted without further washing. He also recommends the addition of 3 per cent. of borax to the mountant, and states that many professionals have already proved the value of this addition.

### Phosphore cent Printing Paper.

According to a French patent, No. 350,289, of R. Bau, the process of preparing a sensitive printing paper in which images in phosphorescent sulphides are obtained, has been seriously advanced. An abstract of the specification in the journal of the Society of Chemical Industry, gives the following description:—One cubic decimetre of the paper pulp is mixed with 150 grammes of calcium sulphide, 30 grammes of zinc sulphide, and 20 grammes of strontium sulphide.

The paste is made into paper in the usual manner, and this, when dry, is rendered impervious with a lac varnish. The paper is then coated with a sensitive silver emulsion. It gives phosphorescent prints when exposed beneath a negative and finished as usual, but it can hardly be supposed that a film of lac can preserve a sensitive silver emulsion very long from the effects of any substratum of sulphides lying immediately below it.

### Air Bubbles in Modern Lenses

M. Delamarre, dealing with this subject in the current number of the "Photo Gazette," utilises the following figure and explanation. Let O be the centre of an air bubble, and SI the direction of the luminous pencil. From the point O draw the two lines OA and OA', making, with SI, an angle equal to the angle of total reflection, which is about  $40^\circ$  deg. to  $41^\circ$  deg. for most glasses. All rays of light striking the bubble between AB and A'B' cannot penetrate it, but are totally reflected, and the only rays which can

pass are included between AA'. These will be refracted away from the path SI, and cannot form any part of the image, therefore all air bubbles act as opaque bodies. The loss of light by this, however, is very small, and it has been proved by Schott and Gen. only amounts in the worst cases to 0.02 per cent. of the light entering the lens.

### Acid Developers for Bromide Paper.

M. Balagny strongly recommends the use of the following developer for all bromide and gaslight papers. Its advantages are that it will not give greenish blacks or greys; it works slowly, and gives pure whites; it can be repeatedly used:—

Sodium sulphite anhydrous .....	56 grains.
Amidol .....	28 grains.
Potassium bromide .....	14 grains.
Acid bisulphite (com. liq.) .....	274 minims.
Water .....	10 ounces.

### Uviol Glass for Lenses.

Herr Martin, of Rathenow, writes, in the current number of the "Photographisches Wochenblatt," on this subject, and points out that the aperture already attained in portrait aplanats in which the ordinary glasses are used is  $f/3$ . To make such a lens it is necessary to have two glasses, of which the  $v$  difference—that is, the difference of the reciprocals of the relative dispersions—must amount to about eighteen. The difference, however, between the uviol glass and flint of Schott and Co. is only nine, and it is not possible to construct an aplanat with an aperture of  $f/3$  with these glasses. An uncemented lens could possibly be made then the loss of light by reflection from the numerous surfaces would do away with the advantage of the increased amount of ultra-violet light passed by the lens.

Independently of this it is an open question whether for ordinary photography a greater transmission of ultra-violet light would be an advantage, particularly, as pointed out by Martin, that the use

colour sensitive plates and yellow screens is becoming more general. For astronomical work and photomicrography, where colour-rendering is of less moment, lenses made of this glass might be useful.

### Pinacyanol.

Valenta, in the current number of the "Korrespondenz," supports his method (see p. 147), of using pinachrome, and speaks very highly in its favour. He also advised a similar bath of pinacyanol dry plates. When used with collodion emulsion, 4-5 per cent. of 1,000 alcoholic solution of pinacyanol, it gives very good red sensitiveness. Referring to Newton's statement (B.J., 1905, p. 830), that pinacyanol gave a "much faster" emulsion than ethyl violet. Valenta states that he cannot confirm this. Pinacyanol sensitises further to the red than ethyl violet, but the latter when correctly used gives a more vigorous and brilliant action in the red, and gives finer plates than the former. 'This is of the greatest importance in tint-tone work.

## THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

### ANNUAL MEETING.

The Fifth Annual General Meeting of the Association was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday evening, the 9th inst., Mr. T. C. Turner, President, in the chair. The report for the year was read.

### Report.

The removal of the date of the annual general meeting from October to March, effected by the alteration of the rules passed at the last annual general meeting, makes the period covered by the present report seventeen months instead of, as usual, a year. During this period fifty-three new members have joined the association and nine have been lost by death or resignation. These figures would point to a not unsatisfactory increase in the membership, but unfortunately, a large number of names have to be removed from the list because repeated applications fail to produce payment of the next subscription. About sixty will have to be so removed before the commencement of another year. The committee cannot help feeling that such a state of affairs points to a want of interest in the association which is most regrettable, and almost justifies some of the hard things which have been said about the profession as a whole.

The committee have met regularly, and the list of attendances published for the first time according to the revised rule justifies the members in believing that the committee continue their active interest in the work of the association. It is obvious that members being far away cannot attend meetings, but in other ways they are able to promote our interest in their own districts.

Applications for advice continue to be numerous, but too often arise in such a way as to lead the committee to learn how to get out of a difficulty instead of by the member's judicious handling of his case instead of to what to do to avoid the difficulty. It is evident that many members fail to bear in mind that the Association is established for the purpose of assisting them and that they have a right to assistance.

The instructions in copyright matters provided by the handbooks etc. are evidently being assimilated, and cases of infringement are being brought to the Association to deal with an increasing number. These cases have become a great feature in the Association's work, and it has been almost uniformly successful in obtaining satisfaction from the offending parties without recourse to law proceedings.

The Assistant's Certificate Scheme has not been quite so successful as anticipated, and it has certainly not been helped as it might have been by the members at large. In accordance with the announcement made at the issue of the prospectus, the committee, at the close of a year's trial, reconsidered the whole question, and made such modifications as seemed to be required. They would like to see upon members that the success of the scheme is as much dependent upon their recognition of its usefulness as upon that of the committee themselves.

A new feature in the working of the Association has been the introduction of a quarterly Circular, of which three numbers have been published, affording the means of keeping the members in closer touch with the committee and of informing them of what is taking place in the Association.

The thanks of the Association are due to the Royal Photographic Society for allowing the meetings to take place at their house, and to the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY for publishing notices, reports, and other information relating to the Association. The committee also wish to express their indebtedness to the hon. solicitor, Mr. Percy E. Marshall, for the valuable assistance he has rendered them.

In the discussion upon the adoption of the report, Mr. C. H. Skillman asked what alterations had been made with regard to Assistants' Certificates. In reply, the Assistant Secretary read the following extract from the circular containing the notice convening that meeting:—

"In accordance with the notifications of the committee at the time the prospectus was published, that the matter would be fully reconsidered in the light of a year's experience, a sub-committee appointed by the committee invited criticism of the existing scheme from those assistants who applied for prospectuses and went no further. The replies were fully considered, and the whole bearings of the scheme carefully discussed. The information derived from assistants themselves was a valuable help towards the realisation of the defects of the scheme from the employees' point of view, and, beyond that, the correspondence disclosed that the prospectus itself was too elaborate and detailed to be easily understood by the majority of the class to whom it was addressed. In several cases it was perfectly clear that it was entirely misunderstood. It was made abundantly evident that a large proportion of the photographic assistants throughout the country are not capable of classification according to any specialised character of their work, but are employed generally as all-round hands, and also that their earnings are not, as a rule, much more than sufficient to meet the cost of living. It has been decided, therefore, to satisfy the requirements of this class by instituting a new grade of certificate, to be entitled 'The General Assistant's Certificate,' and, in order that there may be no excuse for not applying for the certificate on the ground of its being too expensive, it has been resolved that applicants be charged only a registration fee of 2s. 6d."

"The work of the general assistant being necessarily varied in character, the method of determining the candidates' qualifications adopted with regard to classified assistants cannot very well be applied, and a new method will be adopted. The candidate will be required to state his qualifications, and the certificate will be given for those which are upheld by present and previous employers. There are necessarily some details to be worked out. When these are complete a supplementary prospectus will be published, and applications invited through THE BRITISH JOURNAL OF PHOTOGRAPHY."

Considerable discussion followed on the best means of inducing assistants to apply for certificates, but it was eventually pointed out by Mr. Ellis that it was hardly fair to criticise the scheme before it was published. He did not think the majority of the members had given the committee credit for the enormous amount of time and labour, and the number of discussions which had taken place in formulating the scheme. It had been discussed for fifteen months' at intervals of a few weeks, and talked over from every point of view, with a sub-committee also working at it. They had gone into it very thoroughly, and he thought the members might rely that the scheme they would get would be dependable.

The report was then adopted.

The Hon. Sec. and Treasurer, Mr. William Grove, then read the Treasurer's Report and Statement of Accounts from July, 1904, to June, 1905, showing an increase of £22 over last year's balance.

The President then read an address to the members, for which he was heartily thanked.

The announcement of the officers for the ensuing year was then made. As the number of members nominated to fill the various offices was not in excess of the number required no ballot was necessary.

President: Martin Jacollette. Past-President: T. C. Turner. Members of Committee:—London: F. A. Bridge, Alfred Ellis, Ernest C. Elliott, Herbert S. Fry, Wm. Grove, H. Edmonds Hull, Alex. Mackie, H. S. Mendelssohn, Daniel Prodger, Edgar Scamell, Lang Sims, R. Fellows Willson; Country: G. P. Abraham (Keswick), W. H. Bacon (Newcastle), T. Birtles (Warrington), H. A. Chapman, J. P. (Swansea), Wm. Gill (Colchester), P. Lankester (Tunbridge Wells), F. P. Moffat (Edinburgh), A. F. Mowll (Liverpool), R. W. Robinson (Redhill), T. Rowe (Eastbourne), H. C. Spink (Brighton), G. W. Webster (Chester).

Mr. Turner then left the chair, and, on Mr. Jacolette taking it, invested him with the Presidential badge.

Mr. H. A. Chapman, J.P., Swansea, congratulated Mr. Jacolette on the position he had attained, and was sure he would fulfil his duties faithfully and well. He took the opportunity, on behalf of the association, of proposing a very hearty vote of thanks to Mr. Turner who had so ably fulfilled the duties of President during the past year. He personally had not had the opportunity of meeting Mr. Turner many times, but on each occasion that he had seen Mr. Turner in the chair he had presided with skill and ability that merited their very warmest thanks.

Mr. Ellis seconded, and it was carried with acclamation.

Mr. Jacolette then asked Mr. Turner's acceptance from the committee of a replica of the Presidential badge he had worn in his tenure of office. Mr. Turner, in returning thanks, said he considered it a great compliment to the country members, but he could not also forget the very great personal honour which had been bestowed upon him also.

Attention was directed to a letter which appeared in the current number of THE BRITISH JOURNAL OF PHOTOGRAPHY from Mr. Lang Sims on the question of allowing photographers' assistants a half-holiday during the week. It was a letter which every member should read. The views of several members were given on the question, and Mr. Sims was congratulated on his large-minded letter.

Mr. Sims said he thought it was a question which ought to be settled before the summer arrives, as the holiday was wanted chiefly in the summer. The shops in the big centres all close on certain evenings, and it seemed to him that their assistants should be allowed to join other business assistants in their amusements. He was anxious to see what the profession thought of the suggestion, and get some general action taken. It would be a good thing if the association could bring it about.

The meeting closed after passing cordial votes of thanks to the Hon. Secretary and Treasurer and to the Assistant Secretary.

On the evening previous to the annual meeting the committee of the P.P.A. and some friends dined at the Villa-Villa Restaurant, London, W., when an enjoyable evening was spent in an informal manner. Mr. T. C. Turner occupied the chair, and musical contributions to the entertainment were made by a number of members. The guests included Mr. H. Snowden Ward and Mr. George E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY).

#### THE PROFESSIONAL PHOTOGRAPHERS' SOCIETY OF NEW YORK.

AN open letter to photographers in the United States has been issued by the President of the Professional Photographers' Society, Mr. Dudley Hoyt, of Rochester. As the activities of the New York Society are almost identical with those of the Professional Photographers' Association in this country, we may quote the major portion of the letter as applying equally to photographers on both sides of the Atlantic.

About a year and a half ago, twenty-five men organised the Professional Photographers' Society of New York. At the meeting held in April, 1904, the membership roll contained the names of about one hundred and twenty-five men. These men, naturally, were the leaders in the profession, men in close touch with affairs, and living in the centres of population. At the first annual meeting, which lasted two days, the members became better acquainted with each other than they ever had before, matters of great business interest were discussed, and the foundations laid for a society which in time will number in its ranks every progressive worker in the state.

Since that time many new names have been added, and the interest in the organisation has been intensified. The coming meeting will be held in New York, April 5 and 6. While it will be held at the Hotel Astor, located in the busiest section of the busiest city on the continent, it will be an "at home" affair. The talks will concern "the business," the pictures will be "business" pictures, and everybody that attends will be just "business folks."

It will be a meeting at which everybody will learn something, and from which the members will take home with them a broadened spirit and a better understanding of what their fellow workers are doing.

For instance, instead of the usual mixture of pictures seen at photographic conventions, the exhibition at the April meeting will be modelled along a distinctly new and definite line. Each member

will send us one print, which it is expected will express his opinion as to just how much work and material can be incorporated in a picture to sell for a certain sum, with due regard to the incidental and general expense connected with the up-keep of the studio. Conditions, of course, vary in every community, and the proper basis of fixing a charge for a given picture is largely a matter of local conditions; yet an assortment of pictures on these lines is certain to produce a concrete knowledge of great interest.

To make my meaning clearer, the Executive Board asks every member to send a mounted, ready-to-deliver-to-your-patron picture, that, in the estimation of the sender, is remunerative and satisfactory, with good value, at either 5 dols., 8 dols., 10 dols., 20 dols., or 30 dols. a dozen. Especial interest attaches to the 5 dols., 8 dols., and 10 dols. styles for the reason that they represent a more general average of sale throughout the state, and the members have been requested to be modest in making up their exhibits, so that the greatest number will be benefited.

This is how the plan will work out:—Suppose Mr. A. is a photographer in a town of 5,000 inhabitants. His patrons demand from him a certain picture at, say 5 dols. a dozen. Yet Mr. A. feels that his people are gradually working up to a point where they will stand 8 dols. a dozen, but Mr. A. is at sea as to just how much more of a picture he ought to give for 8 dols. instead of 5 dols. He makes a picture, which he thinks he can produce at a profit at 8 dols., sends it to the exhibition, and there has an opportunity to compare it with twenty or more pictures produced with the same idea in view. Here we have an approximate foundation upon which to base a rate, something that all photographers know the need of only too well.

Of course this exhibition is only going to be a start in the right direction: the text around which the members will build their own particular sermons. The pictures that apply to Mr. A.'s patrons will not necessarily interest those of Mr. B., yet Mr. A. may answer a question put by Mr. B. that will go a long way toward helping him in his particular troubles. The thirty dollar a dozen pictures of the New York City men may interest only the Metropolitan Section, but rest assured that there will be plenty of pictures in the same style you elect to send, so that you need only look for the solution of your own particular problem. In this respect the exhibition will be a selfish one—each man for himself. Understand, the one single aim of the exhibition is to help you to make the picture that you have in mind, and come prepared to ask questions. There will be plenty of men on hand to answer them.

Readers of the photographic papers know the stand the society has taken on the various important issues of the day; how, in the matter of copyright, it has entered the very thick of the fight, and is producing results; of its Labour Bureau, now a strong and growing factor; of the insurance question, of apprentices, and the other problems that confront the studio proprietor.

All of this has but the one end—to convince you that no matter what position you hold in the ranks, you are not doing your whole duty unless you are a member of the organization. You may not feel the need of good fellowship now; the services of the Labour Bureau may seem of little importance today, the "single picture" exhibition, the business talks, the smoker, and the two days' stay in New York, may appear a waste of valuable time from your present view point, but the great wheel of fortune makes many turns during a single year, and these are hurried times. The friend in need to-day is the society. Its strong young hand is extended to you, not for the 3 dols. a year, but for yourself, your influence in the community, and your moral support.

PRESS Photography.—"Can any reader give me the addresses of any press photographers in New Zealand and Australia?" This request is put to us by a reader, Mr. G. Austin, of 26, Elmhurst Mansions, Clapham, S.W. Perhaps anyone able to do so will reply to him.

Fox, Talbot, and Company, Limited.—Capital, £2,000, in 40 shares. Objects: To acquire and carry on the business of manufacturers of the P.O.P., known as the "Talbot Brand" and other photographic papers, materials, apparatus, and appliances, carried on by J. Whitfield and H. Meyer, at 103, Altenburg Gardens, Clapham Common, S.W. No initial public issue. J. H. Whitfield and H. Meyer are permanent directors. Qualification, £700. Remuneration, £2 10s. each per week for first year, afterwards as fixed by the company. Registered office: 85, Clapham Road, S.W.

## THE INTERNATIONAL EXHIBITION IN PARIS.

The following is the letter from M. Gastine, the Commissaire Generale of the proposed Exhibition in Paris. It is addressed to a monthly contemporary, at whose suggestion we are quite agreeable to give it immediate publicity in our columns. M. Gastine's letter is devoted to an explanation of the status of the "Chambres Syndicales," which have officially announced their abstinence from the forthcoming exhibition, and to the alleged reasons which have actuated them. It runs as follows:—

To begin with, it is necessary to explain exactly what the syndicates and societies that are not joining in the Second International Exhibition of Photography, 1906, are.

The small combination of syndicates includes four. The most hostile of the group is the Syndicate de la Photographie, which numbers about 400 members. This number would be rather important if the figures were correct, but the truth is that it includes:—

1. The names of deceased members, and those who have retired from the trade.

2. Members who for many years have had nothing to do with the syndicate.

3. Members who belong to other syndicates, or who are members of photographic societies, but who are not professionals.

To put it briefly, the truth is that this *Chambre Syndicale de photographes* *Portraitistes Professionnels* does not include one hundred real professional photographers. The Department of Seine holds more than 1,000 professionals, among which a large number of the more important firms are not members of this syndicate, and in the whole of France there are over 5,000 professionals.

It may be interesting to know that the resolution not to join in the International Exhibition which I am now organising was not the outcome of a referendum including all the members, but only the decision of a meeting of from fifty to sixty members, that is the minority, who pretend to dictate to France and the foreign countries general abstinence, even though it were detrimental to the progress of photography in general and the private interests of everyone.

Another group that has decided not to join is the Syndicates of the manufacturers and Dealers in Photographic Goods. This syndicate is not so hostile as the previous ones, and it does not include many more than 300 members for the whole of France. Its list of members includes such people as do not any longer belong to it, or who have ceased business, but these latter are fewer than in the previously-mentioned list, namely, the professionals. It also includes members of photographic societies who are neither manufacturers nor dealers, though taking it as a whole the large majority of this 300 odd are either dealers or manufacturers. This syndicate, however, like the first, is very far from representing the whole of the industry and commerce of French photography, and, like the first-mentioned syndicate, its decision not to join was made at an ordinary meeting only, which, as a rule, does not count more than fifteen to thirty members at most. The decision, therefore, carries less weight even than that of the professional group.

As regards the two last antagonistic groups of syndicates—the syndicate of Photo-Engravers and the Postcard Publishers Syndicate—these are only made up of a very small number of firms, and the largest postcard publishers are not members of the latter. These syndicates are entirely in the hands of their committees, for the greater part of the members never attend any meetings, so that the committees have very easily been able to decide not to join as a group in the exhibition I am interested in. They have, however, no legal or moral power of preventing any of the members joining on their own behalf. The best proof I can give that this decision is only limited to the syndicate as a whole is the fact that I am in possession of written agreements to join the exhibition from some of the most important firms, notwithstanding the decision of the syndicates not to join.

To illustrate my previous statement, I give you hereunder a copy of a very sympathetic and flattering letter that I received from one of the most important firms belonging to one of these syndicates; indeed, it is one of the most prominent in France. This letter is dated March, 1906, long after all the votes had been taken, and the publicity given to them by the *Chambres Syndicales*. It runs:—  
We are in possession of your circular letter, and beg to thank you for kind remembrances. We shall be very pleased to be one of the members of one of your Admission Committees, and will give you all

the assistance we can in this most interesting undertaking of yours. —Auguste Lumière, Lyons, March 1, 1906."

We have secured this firm as one of those taking part in the exhibition.

As regards the photographic societies—*La Société Française de Photographie*, et *Le Photo-Club*—each of these two numbers about 500 members. These numbers include, however:—

1. The majority of the members of the two syndicates.

2. Each society includes most of the members of the other one.

It is easily explained, therefore, how these groups have the same spirit, seeing that they are made up of the same people. Under the names of about half-a-dozen different syndicates or societies one finds the names of the same people. Six committees closely united against all strangers superintend 600-700 members, with the aid of about sixty prominent members, without consulting them, or rather try to do so in theory if not in reality.

To continue, it is necessary to understand the real reasons of this combined decision not to join, which has been so widely published both in France and in other countries.

The reason for this hostility is as follows:—The groups which have been referred to pretend to be the sole controllers of the photographic world, in France, disregarding the fact that they are only interesting to a very small portion of the photographic world. If you will only examine the General Classification of the Second International Exhibition of Photography, 1906,\* you will see that it includes fourteen groups, out of which the above-mentioned syndicates and societies only represent six.

The public bodies and persons taking part in the eight sections include the Conservatoire National des Arts et Metiers, the Observatoire Nationale of the College de France, Museum d'Histoire Naturelle, Institute Pasteur, the Sorbonne, the Ministry of Public Instruction, the Service des Monuments Historiques (a State Department which is part of the Ministry of Beaux Arts), the Imprimerie Nationale, the Service Anthropometrique du Dr. Bertillon, M. Rene Baschet (editor of the journal "L'Illustration,"), and M. Adolph Brisson, editor of the journal "Les Annales Politiques et Littéraires."

I have also the help of such State Service Establishments as are under the control of the Ministries of Colonies, Public Works, Agriculture, War Office (War Geographic Service), Admiralty, Naval Building Service, the Town of Paris Museums, Carnevate, Cernuschi, Calliera, Guimet, etc., etc.

What are the hostile syndicates and societies as compared with all these?

## THE 1905 KODAK COMPETITION.

The award list for this competition, in which money prizes to the total of £400 were offered by the Kodak Company, has now been published. It will be remembered that the competition was divided into "Open" and "Novice" classes, a policy which we learn has been highly appreciated, and has no doubt contributed the enormous number of prints—over 28,000—submitted by competitors in all parts of the world.

The following is the list of successful prize winners:—

CLASS A: OPEN.— $3\frac{1}{4}$  by  $4\frac{1}{4}$ , or larger. First prize, £30: E. Steichen, New York; 2nd prize, £20, Mrs. N. F. Cones, Covington, U.S.A.; 3rd prize, £10, Alfred Stieglitz, New York; 4th prize, £5, J. Dolman, Philadelphia, U.S.A.; £2 each and Honourable Mention, Mrs. M. A. Wiggins, Salem, U.S.A., Miss Nellie Coutant, Crawfordsville, U.S.A., Miss A. W. Brigman, Oakland, U.S.A., Miss E. A. Wheldon, Leanington, Helen P. Gatch, Salem, U.S.A., F. H. Kelly, London, N.W., G. A. Lee, Baltimore, U.S.A., S. C. Durst, Cincinnati, U.S.A., Wm. S. Rice, Stockton, U.S.A., Dan. Dunlop, Motherwell, N.B.

CLASS B: OPEN.— $3\frac{1}{4}$  by  $3\frac{1}{4}$  or smaller. First prize, £20, M. E. Brockbank, Southport; 2nd prize, £10, J. M. Browning, Bridge of Weir, N.B.; 3rd prize, £5, Mrs. G. A. Barton, Birmingham; £2 each and Honourable Mention, H. H. Burns, Edinburgh, E. B. Vignoles, London, W.C., J. Hamilton, London, W., J. S. Neary, Trenton, U.S.A., Mrs. Myra A. Wiggins, Salem, U.S.A.; £1 each and Honourable Mention, Clarence Ponting, Scarborough, Rev. R.

\* Printed in our issue of January 26.—EDS. B.J.P.

E. Vernon Hanson, Dublin, H. B. Conyers, Urbana, U.S.A., E. Horner, Media, U.S.A., Mrs. N. F. Cones, Covington, U.S.A.; No. 1 F.P.K. and Honourable Mention, J. Burns, Edinburgh.

CLASS C: OPEN.—Enlargements. First prize, £30, Dr. A. Miller, Warwick; 2nd prize, £20, E. Steichen, New York City; 3rd prize, £10, Laura A. Armer, Berkeley, U.S.A.; £4 each and Honourable Mention, Alfred Steglitz, New York, Annie W. Brigman, Oakland, U.S.A., Harold Baker, Birmingham, W. Shaw, Chicago, U.S.A., H. B. Conyers, Urbana, U.S.A.

CLASS D: NOVICE.— $\frac{3}{4}$  by  $\frac{4}{4}$  or larger. First prize, £20, Harriet Lynam, Concord, U.S.A.; 2nd prize, £12, W. A. Wilson, Idaho, U.S.A.; 3rd prize, £8, Elizabeth M. Rise, Stockton, U.S.A.; £2 each and Honourable Mention, R. Mathée, a' Soindres, Paris, T. W. Allen, Paris, U.S.A., Dr. A. R. Benedict, Montclair, U.S.A., B. W. Guppy, Woodford, U.S.A., F. A. Tinker, Sheffield; £1 each and Honourable Mention, Miss H. Cumpbell, Abbey Lier, Ireland, Mrs. Henrietta Hasbouch, Davenport, U.S.A., Miss S. Jamieson, Cheltenham, Miss J. Murray, Wolverhampton, J. W. Burmester, Sutton, Surrey.

CLASS E: NOVICE.— $\frac{3}{4}$  by  $\frac{3}{4}$  or smaller. First prize, £15, Miss S. V. Atwell, Worcester, U.S.A.; 2nd prize, £8, Johannes Noack, Berlin; 3rd prize, £5, Arch. McVicar, Greenock; 4th prize, No. 4 Cartridge Kodak, Miss E. Barratt, Kelvedon, Essex; 5th prize, No. 3A Folding Pocket Kodak, Dr. F. W. Robertson, London, S.W.; No. 3 Folding Pocket Kodak and Honourable Mention, E. M. Chapman, Scarborough, W. E. Angear, Roborough, S. Devon, Miss E. H. Southwell, Corsica, Miss Jean Stirling, Chicago, U.S.A., Chabert de Brack, Paris, Jennie Ray, Spokane, U.S.A., Mrs. M. P. Banks, Maida Hill, London, W., Mrs. S. M. Hitchcock, Yonkers, U.S.A.

CLASS F: NOVICE.—Brownie Pictures. First prize, No. 5 Cartridge Kodak, Mrs. A. C. Morgan, Denver, U.S.A.; 2nd prize, No. 4 Cartridge Kodak, Miss G. M. Cooper, Preston; 3rd prize, No. 3A F.P.K., M. J. Walker, Monroe City, U.S.A.; 4th prize, No. 3 F.P.K., Miss J. H. Todd, Tarrytown, U.S.A.; 5th prize, No. 2 F.P.K., Miss Dorothea Seton, Edinburgh; No. 1 F.P.K. and Honourable Mention, F. N. Henry, Philadelphia, U.S.A., Mrs. M. Bayuk, Philadelphia, U.S.A., Miss J. Willard, Oakland, U.S.A., Miss S. Shipley, The Mount, Lincoln; No. 0 F.P.K. and Honourable Mention, O. Goldsmith, Great Bookham, Surrey, A. W. May, Upper Tooting Park, London, S.W., Mrs. W. H. Gardner, Buckport, U.S.A., H. G. Couthbert, Philadelphia, U.S.A., Pierre Lejard, Paris; No. 2 Plico and Honourable Mention, Edward Teas, Deal Island, U.S.A., Mrs. K. Appleyard, West Kensington, Constance Parsons, Haresden, London, N.W., W. C. Huff, Belleville, U.S.A., A. B. Pascoe, Woking, Surrey.

## Exhibitions.

### NOTTINGHAM CAMERA CLUB.

THIS fifth annual exhibition, which opened on Wednesday, the 14th, and remains open until to-morrow, is a decidedly better show than even last year's. While the open classes are very strong, with work from many well-known exhibitors, the most satisfactory feature of the exhibition is the amount of really capital work from members, including many who are scarcely beyond the stage of novices. If the promise can be maintained the Nottingham Camera Club should take its place amongst the most successful of exhibiting societies. Perhaps the most interesting and versatile of these younger men are Mr. Will Darcy, who scores in two classes; Mr. F. N. Radford, who scores in an open, as well as in a members' class; Mr. Arthur Black, who scores twice, and Mr. S. W. Barlow Vines, the secretary, who takes one of the plaques in the exceedingly strong Class G.

The following is the award list in the open classes:—

Landscape, Seascape, and River Scenery: Bronze Plaques: No. 13, "The Farm Road," A. Bayley; No. 103, "Sunshine and Shadow," T. H. Radford; No. 67, "Evening after Rain," W. H. Fowkes; No. 81, "The Last Leaves of Autumn," Dan Dunlop. Hon. Mention.—No. 95, "On Lago Maggiore," Jas. E. Latham; No. 48, "In the Path of the Storm," Thos. Wright; No. 43, "The Vesper Hour," Bertram C. Wickison. Portraiture, Animal, and Figure Studies.—Bronze Plaque.—No. 153, "Onora," Miss Marian Silverston; No. 167, "Head of a Man," Andrew Paterson. Special Bronze Plaque: No. 187,

"Finishing the Plaque," C. B. Howdill, A.R.I.B.A. Hon. Mention: No. 122, "A Portrait," Chas. E. Beale; No. 183, "A Volendam Fisherman," Herbert Bairstow; No. 144, "The Captive" (by courtesy of the "Sketch"), James Clark. Flowers, Fruit, and Still Life.—Bronze Plaque: No. 206, "Iris," E. Seymour. Hon. Mention: No. 197, "Gooseberries," Percy W. Morris; No. 207, "A Bramble Spray," Fred Judge; No. 210, "Japanese Anemones," Dan Dunlop. Architecture, and any Subject, other than Classes A, B, C.—Bronze Plaques: No. 249, "Until the Day Breaks," S. G. Kimber; No. 252, "An Arcaded Street," S. L. Coulthurst; No. 213, "Going to be Shaved," Sidney R. Stevenson. Hon. Mention: No. 231, "St. Leonard's Hospital, York," Rev. H. R. Campion. Special Mention: No. 222, "Group of Diatoms," W. H. Pratt. Lantern Slides: Bronze Plaques: A. Bailey, Fred Judge. Hon. Mention: J. W. Charlesworth, Thos. Wright. Special Mention: Francis Ward, D. G. H. Rodman.

### WOLVERHAMPTON PHOTOGRAPHIC SOCIETY.

THE Wolverhampton Photographic Society held its fifth annual exhibition last week. Among the notable exhibits were a number of Dutch scenes, contributed by James Gale, who also exhibited some artistic impressions of London, principally from the river's aspect. Neither of these pictures was, however, exhibited for competition. Mr. Thomas H. Cox also had some pleasing Dutch views—villages and waterways, interior studies, and a picture entitled "A Stitch in Time Saves Nine." Other creditable work was "Ringing a Wheel," by Charles J. Reade; "Woman's Work," by T. H. Cox; and "Reverie," by E. H. Griffin. Mr. Harold Holcroft contributed a fine study—a foreign street scene—entitled "The Rain it Raineth Every Day." There were some excellent cloud studies, Mr. F. C. Hickman being represented by a view on Conway shore. The work of the society, as a whole, exhibits marked progress.

### FORTHCOMING EXHIBITIONS.

February 24 to March 31, 1906.—Birmingham Photographic Society. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreve Street, Birmingham.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March, 1906.—Leicester and Leicestershire Photographic Society. Hon. Secretary, W. B. Woodland, 18, Beckingham Road, Leicester.

March, 1906.—Rugby Photographic Society. Hon. Secretary, R. N. Myers, 13, Bridget Street, Rugby.

March, 1906.—Photographic Society of Ireland. Hon. Secretary, H. V. Yeo, 194, Clonliffe Road, Drumcondra, Dublin.

March 6-20, 1906.—Glasgow Southern P.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 14-17, 1906.—Nottingham Camera Club. Hon. Secretary, S. W. Barlow Vines, Market Chambers, South Parade, Nottingham.

March 19-24, 1906.—Sunderland Photographic Association. Hon. Secretary, William E. Kieffer, Stirling Street, Sunderland.

March 24-31, 1906.—Leicester and Leicestershire Photographic Society. Entries close March 10. Sec., R. Warden Harvey, 18, Market Place, Leicester.

March 27, 1906.—Brentford Photographic Society. Entries close March 9. Secretary, Oliver Gluyas, 89, Windmill Road, Brentford, Middlesex.

March 27-28.—Worthing Camera Club. Sec., E. F. H. Crouch, 11, South Street, Worthing.

March 31 to April 10.—Salon of the Photo Club of Nice. Address the Secrétaire-Général, 20, Rue St. Francois de Paule, Nice.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blenheim, Coatbridge.

April 2 to 7.—Photographic Society of Ireland. Secretary, W. F. Cooper, 194, Clonliffe Road, Drumcondra, Dublin.

April 16-21.—Redcar Photographic Society. Entries close April 9. Secretaries, W. H. Tayler, Esplanade, and J. M. B. James, 4, Elton Street, Redcar.

April 18 to 20.—Southend-on-Sea exhibition. Hon. Sec., J. Archer, 24, Ashburnham Road.

# Patent News.

Process patents—applications and specifications—are treated in *Photo Mechanical Notes*.

The following applications for patents were made between February 23 and March 3,—

PRINTING.—No. 4,697. Improvements in paper rolls as used in copy-

ing presses, photographic printing machines, etc. George Bluen, 18, Southampton Buildings, London.

COLOUR-GRAPHY.—No. 4,714. Improvements in colour-photography. Newton H. Hyde, 40, Chancery Lane, London.

PRINTING FRAMES.—No. 4,730. Improved photographic printing frame. John Batty, 124½, Wills Street, Lozells, Birmingham.

PRINTING RACKS.—No. 4,735. An improved folding photographic plate draining rack. John Batty, 124½, Wills Street, Lozells, Birmingham.

EXPOSING PLATES AND FILMS.—No. 4,992. Improvements in and means of carrying and exposing sensitive photographic plates or films in the camera. Joseph William Kay, 6, William Street, Colne, Lancs.

COLOURED PHOTOGRAPHS.—No. 5,109. An improved means of pro-

base frame are mounted two quadrangular telescopic frames E and F, for supporting the printing frames or other accessories necessary in the operations. Each telescopic frame is provided at one end with a folding support against which rests the printing frame, easel, or other apparatus as required. Each telescopic frame is free to move either together or in a direction opposite to each other. Also, one of the sides of each of these telescopic frames is notched and graduated in inches, so that the printing distance, or the distance between the printing frame and the

source of light, giving the best results may be noted and registered so that no matter what number of repeats may be required at a subsequent period, they can, on reference to the register, be quickly and accurately reproduced. Arthur James Lambert, 250, Barkerend Road, and Chas. Henry Land, 15, Alma Place, Thornbury, Bradford.

CINEMATOGRAPHY IN COLOURS.—No. 9,465, 1905. The object of the invention is to provide a self-contained apparatus of compact arrangement and small bulk for exhibiting animated pictures in their natural colours, and which requires only a small amount of light such as an ordinary oil lamp, and can be constructed in a portable form adapted for home use, and forms an improvement on the invention described in Letters Patent No. 3,729, dated

ducing coloured photographs. Albert Beaumont, 23, Bridge Street, Hawick, N.B.

PRINTING ACCESSORIES.—A photographic appliance to be used in conjunction with a camera for the purpose of copying, enlarging, or reducing. George Smorthwaite, 2, North Croft Villas, Englefield Green, Surrey.

PRINTING FRAMES.—No. 5,182. Improved photographic printing frame. William Graham Brown, Cordiner Manse, Lesmahagow, Lanarkshire.

SLIDES AND PLATE CARRIERS.—No. 5,212. Improvements in slides and plate carriers for photographic cameras. Frederick McKenzie and George Wishart, 65, Chancery Lane, London.

PRINTING PLATES.—No. 5,241. An improved method of packing photographic plates and films. Cecil William Cunningham, c/o the Imperial Dry Plate Co., Ltd., Cricklewood, London.

STEREOSCOPIC PHOTOGRAPHY.—No. 5,267. Improvements in method of and apparatus for taking stereoscopic photographs. Bug Ges n.b. H. zur Verwertung von Erfindungen und Gustav Barnack, 40, Chancery Lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PRINTING AND COPYING STAND.—No. 14,052, 1905. The invention consists of a suitable outer base frame, or slide, A. Upon this

February 17, 1903, and granted to Benjamin Jumeaux and William Norman Lascelles-Davidson. A single prism is disposed behind the lens so as to intercept some of the rays from the image, which being refracted, form a second image. *a b* is the object, *c* the lens of the camera, *d* a prism, *e* a yellow orange colour screen, *f* a blue red screen, and *g* the focus of the lens *c*. The ray *a h* is refracted by the lens *c* and passes through the focus *g*, and through the screen *e*, the focussed image of *a* appearing at *j*. The ray *a k* passes through the centre of the lens *c* is not refracted thereby, and strikes the prism *d* and is refracted. The ray *a k m* passes through the screen *f*, and the image appears at *n*. All rays from *a* which are not intercepted by the prism *d* pass through the point *j* and form the image of *a*; similarly all rays from *a* which are intercepted by the prism *d* are refracted and a second image of *a* is formed at *n*. In the same manner the ray *b o* is refracted by the lens *c*, the ray *o p* passing out of the lens in the direction of the focus *g*, but it is intercepted by the prism *d*, passes through the screen *f*, and the image of *b* appears at *q*. The ray *b k* passes unrefracted through the centre of the lens *c*, through the screen *e*, and an image of *b* appears at *r*. All rays from *b* which are intercepted by the prism *d* pass through the point *q* and form an image of *b*; similarly, all rays from *b*, which are not intercepted by the prism *d*, pass through the point *r*, and form a second image of *b*. Rays from points intermediate between *a* and *b* are refracted by the lens *c*, or the lens *c* and the prism *d*, so as to

pass through the screen *e* or the screen *f*, and produce images intermediate between *r* and *n*. The screens *e* and *f* are arranged so that all rays which are not intercepted by the prism *d* pass through the screen *e*, and all intercepted rays pass through the screen *f*. As shewn, the prism is disposed between the lens and its focus, and it is placed half-way across the lens with its apex on the centre line of the lens. The apparatus used may be that described in the previous Patents No. 22,954 of 1893, No. 22,928 of 1896, No. 21,649 of 1898, or No. 13,883 of 1900, and the prism used is preferably a prism of 20 degrees. The two images *j*, *r*, *n*, *g*, of the object *a*, *b*, are similar to all appearances, and may overlap slightly according to the position of the prism *d*. In use the orthochromatic film is passed through the plane *r*, *n* so as to receive the images side by side on the film; that is to say, assuming the diagrammatic drawing to be a plan the film would pass vertically, or if the film is to pass horizontally the drawing must be taken to be in elevation. In projecting the pictures the relative coloured screens with which the pictures were taken, are used, only of lighter degree, taking into consideration the colour and density of the transparencies and the light to be used. In projecting, the prism used is of greater angle, so as to produce greater deviation, and consequently a magnified projected image. For more accuracy in obtaining the varied colour tones, shades, and distance, the above described arrangement may be multiplied, the screens being of different colours; for instance, blue and yellow screens may be used for one pair of pictures, red and green for another pair, and violet and orange for a third, the same screens being used for projection. William Friese Green, 20, Arundel Street, Kemp Town, Brighton.

**ISO ROLL SCREENS.**—No. 11,765, 1905. The invention consists in the method of forming an iso screen in long strip form and tinting the gelatine or like screen of strip formation with various coloured stains: mounting such screen on rollers so that it can be adapted with regard to the lens so that the greater non-actinic density can be given to the ultra-violet parts of the subject being photographed. Such screens are to be employed singly or in combination according to the subject being photographed. The screens are mounted on rollers or frames, and in some cases an adjustable frame may be constructed to carry in the whole or a portion of their space a sheet or sheets of gelatine or similar material tinted in various densities and contours. For portraits, for example, a portion of the screen is tinted in graduation or not, from a clear or light tinted centre to the edge of the section of the screen, so that after exposure and development on printing of negative, the background in the positive may be very dark or gradually graduated off to a dark colour. This principle may be applied to subjects when photographed for the purpose of conversion into lantern slide transparencies, as this screen will keep back the action of the light on the sensitized plate, and thus produce clear glass in the negative which, in its turn, will produce an opaque mask on the lantern transparency. The same principle may be applied for vignetting landscape pictures, tit-bits of architecture, and the like. When photographing interiors, it has been found that little or no halation occurs when a yellow light filter has been used. This is objectionable, however, where a dark interior is being photographed, as a prolonged exposure is necessary, thus taking up, it may be, several hours, but by adjusting a section of the roll screen, whereon is placed a yellow spot, to the position of the highest light, less of the ultra rays penetrate the lens and a better printable density and less halation is thus secured, the ultra rays being absorbed. Harry Ernest Staddon, 143, Blythwood Road, Goodmayes, Essex.

**CINEMATOGRAPHS.**—No. 10,602, 1905. The claim is for the combination with the feed dog of an adjustable roller over which the film passes after leaving the feed dog. Any suitable means can be provided for effecting the adjustment of the roller, such, for example, as a rack and pinion. It will be understood that the position of the film in the gate, that is to say, with respect to the lens, can be adjusted by altering the position of the adjusting roller, since the position of this roller determines the length of film loop between the gate and the said adjusting roller, that is to say, controls the length of film which is fed through the gate by the dog as it revolves. Alfred Wrench, 50, Gray's Inn Road, London.

## New Books.

"Les Objectifs d'Artiste," by L. de Pulligny and C. Puyo. Published by the Photo-Club de Paris, 44, Rue des Mathurins, Paris. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C. Price, 5s.

This work, to which reference was made last week, is divided into two sections; the first we may call the practical exposition of the aims and use of anachromats, the second being devoted to the mathematical calculation involved in the use and construction of the anachromatic lenses.

The details given in the first section are such that anyone would be able to mount up these lenses either in home-made arrangements or in existing mounts which he might have, and in particular to make the semi-anachromat, in which the front lens of a Petzval portrait lens is used. The working data as to the correction of the lens by racking-in, etc., are very complete.

The second part will probably not be of so much interest to the general reader or user of these lenses, but even in this part, at the end of every chapter, is a practical resumé of the conclusions mathematically arrived at which will be extremely useful.

The work may be briefly stated to be a full and detailed amplification of the views and statements put forward in our last issue by M. de Pulligny and Major Puyo, and it is illustrated with some half-tone illustrations which certainly bear eloquent testimony as to the use of these lenses, and numerous diagrams are scattered throughout the text.

"Colloidon Emulsion." By Henry Oscar Klein. London: Penrose and Co. 5s.

The growth of colloidon emulsion in favour with process workers has emphasised the need of a text book on its use for some time past. In responding to the demand for such a volume, Mr. Klein has taken a mid course between an elaborate theoretical and historical treatise and a manual which dealt only with rule of thumb formulae and methods. He tells his readers enough of the theory and chemistry of the process for them to understand the practice; but after all, the practical part of the volume is the one which invites consultation and criticism. In it the author gives directions for the use of colloidon emulsion for ferrotype work, for lantern-slide making, and for the wood engraver. The most important application, however, of emulsion are in colour-photography, and Mr. Klein fully states his experiences in the use of emulsions, orthochromatised with dyes for the various direct and indirect colour processes. It seems a little unfortunate that the book was written in August 1905, just before the introduction of the new isocyanine, pincyanine, and so, though not published until now (nearly six months after), there is no mention of this dye, which appears to be superior to all other red sensitisers, and rapidly superseding them. In regard to these isocyanines, Mr. Klein states that the speed of emulsion treated with them may be increased by bathing with a neutral solution of silver nitrate, but this has not proved so in our trials and the practice has other disadvantages.

In the chapter on "Defects" the author, in speaking of Mr. Farmer's experiments, as detailed in his R.P.S. paper on "Irradiation," takes it for granted that this effect is halation, commencing the paragraph, in fact: "Halation, or irradiation, is a defect." We wonder what Mr. Farmer will think of this, since he was most particular to claim that the phenomenon he described is quite distinct from halation, and surely he is very far from regarding it as any defect.

The volume contains nine plates showing properties or defects of emulsion negatives, and devotes one chapter to the preparation of ordinary and orthochromatic emulsions, which section, we would say, might very well have been more than a compilation of other people's formulae.

"A Guide to the New House of Commons," published as a supplement to "Hazell's Annual," reaches us from Messrs. Hodder and Stoughton, by whom it is issued at sixpence. The "Guide" contains particulars of the past and present state of political parties, biographies, and addresses of M.P.'s, and other Parliamentary information.

The "Agenda Lumière" for 1906 reaches us from Messrs.

authier Villars, by whom it is published for the Lumière Company, of Lyons. It contains a large number of tables and formulæ, and a list, with references, of the numerous papers on photographic and chemical subjects emanating from the Lumière laboratories since 1887.

## New Materials.

Richmond" Self-Toning P.O.P. Made and Sold by Morgan and Kidd, Kew Foot Road, Richmond, Surrey.

On another page in this issue we report a lecture delivered before the London society by Mr. Ernest Morgan, in which are explained the properties of a new paper now being placed on the market by the established firm of Morgan and Kidd, the original makers, it will be remembered, of bromide paper. The paper is of the self-toning description, and much as papers of this kind have been used and abused, the new introduction is one with certain very strong and, in our opinion, very important claims to notice. In the first place a colloid or combination of colloids is used as the vehicle of the sensitive salts: in the second the toning action is regulated in a very precise manner chemically.

The carrier of the sensitive silver salts is not gelatine or collodion, but a mixture of boiled starch and agar-agar. The film on the paper thus made is extremely porous or equally non-porous by adding the proportion of these two substances. As manufactured, the film is considerably more porous than gelatine is aimed at, and the need for washing before and after the tone-fixing operation is thus considerably reduced. From our experience the paper appears to be about the usual rapidity of P.O.P., and it requires about the same amount of over-printing. The subsequent operations are three in number:—

1. Preliminary washing—5 minutes.
2. Fixing (with toning)—10 to 15 minutes.
3. Washing—30 minutes.

Simple as this manipulation is, it is nevertheless designed to carry out the special aims of the makers, viz., to remove free acid before the paper enters the hypo. bath, and to safeguard the hypo. bath against any traces of acid which may escape removal by washing. The first minutes' wash in several changes, or in running water, will bring the paper to the first condition, and the second is ensured by adding a solution of bicarbonate of soda to every pint of the fixing bath. These operations which require no extraordinary care on the part of the user, are made to bring the print into the condition favourable to permanent gold toning. The makers very properly lay stress on the importance of removing the opportunity for sulphur toning to place from the action of acid in a paper on the hypo. bath, they regard the power of a self-toning paper to tone readily as well washing as a proof of the legitimate nature of the toning operation. Our own experience is that the "Richmond" paper gives the best satisfactory results. After complete washing it tones evenly on the surface in the hypo-bicarbonate bath, and in the case of ten minutes—longer, if the bath is chilled—tones to a warm black in the finished print. The operation is so extremely simple, and the method, in our judgment, so entirely in accordance with our knowledge of the chemistry of toning and fixing, that we do not hesitate to describe the paper as a great and noteworthy advance in printing processes. Like other self-toning papers the "Richmond" paper lends itself to the production of cold blacks as well as of a range of warm colours by platinum toning. The method, however, is something of a departure. The prints are developed, without washing, in—Hydrochloric acid, 1 oz.; water, 1 pint, for five minutes, and, after a rinse, toned in a plain solution of chloroplatinite of potassium (1 grain in 5 ozs. of water). After a high washing they are fixed and washed as usual. The purpose of the strong acid bath is to convert all the free silver into chloride thus prevent the yellowing of the high-lights after the ammonia bath. The acid, no doubt, accomplishes this purpose by preventing the formation of insoluble chloroplatinite of silver. The gelatine film of the paper is able to stand the application of the strong acid solution.

As regards the mechanical properties of the prints, they may be developed in warm water without fear of softening, and in like manner

can be blotted off and dried by heat. They can be given a high gloss by rolling, or glazed by the collodion process. In appearance the prints resemble "fine albumen or collodion surface—the glossy is not very glossy, and the matt not at all rough, but both surfaces are well suited to the average run of negatives. The paper is sold at 1s. 11d. per two sheets, 24½ x 17, or in twelve quarter-plate pieces for 6d.

A NEW plate, the "Amauto," or self-developing, has been introduced by the Ilford Company. The developer is carried on the plate, and the only operation needed for development is the immersion of the plate in a 10 per cent. solution of washing soda. The price of the "Amauto"—on which we shall report in due course—is 2s. per dozen, in quarter-plate size.

MESSRS. Elliott and Sons, Limited, have added to the "Barnet Ortho" plate, another to be known as the "Medium Ortho." The new plate, which is stated to be of medium speed, will be reviewed in these columns in due course.

## CATALOGUES AND TRADE NOTICES.

PLATINUM recovery from waste papers and the residues from developing solutions is a department of their business of which Messrs. J. Blundell and Sons, 199, Wardour Street, W., are making a specialty. The charges are based on a scale which should prove remunerative to photographers working the platinotype process.

A CIRCULAR of new Busch cameras for 1906 is newly issued by the Emil Busch Optical Co., 35, Charles Street, Hatton Garden, London, E.C.

## News and Notes.

BLenheim Club.—Next Thursday the lecture at the Blenheim Club, St. James's Square, is on "English Royal Heraldry," by Mr. Cyril Davenport. The lecture is the last but one of the present series, arranged for February and March.

A FIRE broke out last week in a bedroom of the premises of Mr. W. Harrison, photographer, 115, Main Street, Bray, Ireland. It originated through a fire screen igniting a cabinet.

DEATH in a Leeds Studio.—Mr. S. H. Stenson, aged sixty, of Burley, Leeds, was visiting the studio of Mr. Allen Nield, photographer, Queen's Arcade, one day last week, when he was suddenly seized with illness, and died from heart failure before medical assistance could be obtained.

A NEW studio has been opened by Mr. Walter Smith at Station Street, Spalding, to replace the older one in Priory Road.

THE entire business of Messrs. H. and W. Green, Crown Photo-Manufactory, Rotherham, including the premises, machinery, trade names, designs, etc., has been purchased by the senior partner, Mr. H. W. Green, who for some years past has entirely managed the business.

How to Make a Developer.—A choice example of finesse in formula making is that of a daylight developer patented in Holland:—

Potassium metasulphite .....	120 parts.
Sodium sulphite .....	240 parts.
Potassium ferrocyanide .....	5 parts.
Citric acid .....	7.3 parts.
Potassium carbonate .....	120 parts.
Sodium carbonate .....	60 parts.
Potassium hydrate .....	30 parts.
Potassium bromide .....	5 parts.
Quinol .....	90 parts.
Metol .....	10 parts.
Resorcin .....	10 parts.
Sulphurous acid .....	20 parts.
Phenolphthalein .....	24 parts.
Water .....	3,000 parts.

It would be interesting to calculate the chemical composition of the bath after the various acids and alkalis have reacted.

**A PHOTOGRAPHER Poet.**—The "Standard's" Paris correspondent reports the death of Etienne Carjat. The news means little to the new generation. But for those whose memory goes back to the Second Empire it means the passing away of a curious profession, or rather of a curious combination of professions, the poet-photographer. Carjat was not a great poet, indeed he might very well have drawn from the funds of the poets' newly-formed society if he had lived a little longer. But with two irons in the fire he was able to make his hat shine, although poor. A top hat was part of his stock-in-trade, for without one he could not attend funerals at Père Lachaise. He followed the example of the brothers Lionnet, using both photography and poetry to record the last journey of great men—and sometimes of small ones, too—and thus he earned his living. He gave up this occupation some years ago, and received a State pension.

**THE Photographic Convention.**—As will be seen from the report under "Societies' Meetings," the Herefordshire Photographic Society are in hopes of the Photographic Convention visiting Hereford in 1907. A formal invitation has been extended by the Mayor (Mr. Edwyn C. Gurney), and the proposition will be laid before the annual meeting of the Convention at Southampton in July, when it is hoped that members of the Herefordshire Photographic Society will be present to support the Mayoral invitation.

**YORKSHIRE Photographic Union.**—The following are the newly-elected officers for 1906: President, F. Atkinson (Hull); Vice-Presidents, Messrs. John Cook (Huddersfield), Thos. Heaps (Keighley), C. B. Howdill (Leeds), Percy Lund (Bradford), and Percy Sheard (Leeds); Hon. Treasurer, Alex. Keighley; Hon. Sec., Lantern-Slide Section, W. H. Houghton; Hon. Sec., Print Portfolio Section, Lionel Dickinson; Hon. Business Sec., Ezra Clough. The following gentlemen were elected as the Official Judges of the Union: Messrs. Godfrey Bingley, Gilbert Foster, R.B.A., Alex. Keighley, Percy Lund, and Harry Wanless.

**THE late J. J. Vezy.**—It is with great regret we learn of the sudden decease last week of Mr. J. J. Vezy. His death took place as he was leaving the Radiographic Hospital at Blackheath, with which he had been actively connected. Mr. Vezy was a member of the Royal Photographic Society, and served on its council from 1899 to 1901. He was a valuable member of the House Committee, and on his initiative the lantern evenings at the society were inaugurated. The deceased gentleman was a man of wide artistic and scientific tastes, and devoted a large share of his leisure to philanthropic works. His demise will be regretted by a large circle of friends and associates.

**SINCE** the publication of last week's articles on "Artistic Lenses," a photographic objective of French manufacture, constructed for pictorial purposes, has been brought to our notice by the sole British agent, Mr. F. C. Clarkson, Colchester. The "Eidoscope," as it is called, is stated to own its "softening" effect to spherical aberration and is thus put forward as suited for pictorial effects at its full aperture of  $f/5$ , and for sharp definition when stopped down to  $f/10$  or  $f/20$ . It is issued in four sizes of foci from  $7\frac{1}{2}$  to 19 inches.

**PHOTOGRAPHY** for the L.C.C.—The London County Council recently invited offers for the general photographic work of the Council from four London firms, and although we are not able to state the amount of work represented by the taking of negatives, it may be interesting to quote the tenders submitted by the four invited firms. The lowest tender—Messrs. Avery's—was accepted by the Council.

Name.	One Negative and two Silver Prints.	One Negative and two Bromide Prints.	One Negative and two Platinotype Prints.
Avery and Co.	s. d. 10 4	s. d. 10 8	s. d. 12 4
Bolas and Co.	10 6	11 6	12 6
The London Stereoscopic Company	12 6	13 6	13 6
Clemson and Hutchinson	13 6	13 6	15 0

**THE United States** alone, according to a daily paper, made 300,000 cameras last year, and the photographic business reaches the respectable commercial total of £4,000,000.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
16	Watford Photographic Society	"Marine Photography." Mr. E. J. Mortimer, F.R.P.S.
16	Aberdeen Amat. Photo. Assn.	"Intensification and Reduction." Mr. Anderson.
16	Colne Camera Club	"Time Development." Demonstrated. Mr. H. Woods.
17	Aberdeen Photo Art Club	Blue Hill, Bridge of Dee.
19	Wildnes Photographic Society	"Methods of Intensification." Mr. G. I. J. Warner.
19	Wallasey Amat. Photo. Soc.	"Development." Mr. R. Tunnicliffe.
19	Heaton & Dis. Camera Club	"Lantern Slide Making by Retraction and Contact." Demonstrated. Mr. A. Stratton.
19	Hastings and St. Leonards P.S.	"A Short Holiday in North Wales." Mr. A. M. Apel.
19	Scarborough and Dis. Ph. Soc.	"Telephotography." Mr. C. P. Goss.
19	Southampton Camera Club	Focus Prize Slides.
19	Leek and District Photo. Soc.	"Worcester and District." Mr. V. Prince.
19	Bowes Pk. and Dis. Ph. Soc.	"Abroad with a Camera." Mr. E. Tappenden.
19	Dewsbury Photo. Society	"The Afterwork of Picture, Stretching, Mounting, and Framing." Mr. Perrin, A.B.I.C.
19	Catford & Forest Hill Ph. Soc.	Amateur Lantern Slides 1905. Photographic Prize Slides.
19	Wandsworth Camera Club	"Combination Printing by Glycerine Method." Demonstrated. Mr. B. H. Baskett.
20	Royal Photographic Soc.	"The Victoria Falls." Mr. J. F. Bass.
20	Sunderland Camera Club	Exhibition of Works by Mr. G. T. Coohay. And Chat on Home Portraiture.
20	Gloucestershire Photo. Society	"Bromide Printing." Demonstrated. Rotary Co., Ltd.
20	Jersey Photographic Society	"Portraiture." Mr. Harold Baker.
20	Newcastle-on-Tyne Photo. Assn.	"The Toning of Bromide Prints and Lantern Slides. The Intensification and Reduction of Negative and Tabloid." Brand of Photographic Chemicals." Mr. Walter P. Wilmough.
20	Colne Camera Club	"Collection of Slides Illustrative of Winter." Messrs. Ogden and Ormerod.
20	Bristol Photographic Club	"The Possibilities of Portraiture in Colour." Mr. S. E. Neame.
20	Darlington Camera Club	"Lantern Lectures." Mr. E. Little.
20	Birmingham Photo. Society	Sale of Apparatus, &c.
20	Manchester Amat. Photo. Soc.	"Copying Prints with a Camera." Mr. F. W. Farrold.
20	St. Helens Camera Club	"With Camera and Notebook." Mr. E. E. Burgess.
20	Otley & Dis. Cam. & Art Soc.	"Enlarging and Finishing." Dr. H. Paterson and Dr. W. H. Helm.
20	Sheffield Photographic Society	Conversational Evening with Demonstrations. "Copying for Postcards, &c." Mr. J. J. Leary.
20	Halifax Camera Club	"Self-toning Paper." Mr. G. Ryley. "Picture Planes." Mr. Perrin.
20	Nelson Photo. Society	"In Search of the Picturesque." Mr. W. H. Houghton.
20	Cardiff Windsor Amat. Ph. Soc.	Velox Papers.
21	Redhill and District Cam. Club	"Carbon Printing." Mr. T. Harrison.
21	Tunbridge Wells Ama. Ph. Assn.	"Nature as Viewed by the Panoramic Camera." Miss Turner.
21	G.E.R. Mechanics' Institution	"Still Life, Flowers, Copying, &c." Demonstrated. Mr. H. W. Bennett.
21	Rotherham Photo. Society	F.R.P.S.
21	Coventry Photo. Club	"Lantern Slide Making." Mr. J. Stamp.
21	Cricklewood Photo. Society	"Practical Lessons." Messrs. Ponsford and Woolacott.
21	North Middlesex Photo. Soc.	"Elementary Pictorial Composition." Mr. H. Barnard.
21	Leeds Camera Club	"In Briland with a Camera." Mr. Oliver G. Pike.
21	Redcar and Coatham Ph. Soc.	"Printing and Toning and Bromide Printing." Mr. A. E. Graham.
21	Coventry Photo. Club	Nominations of Officers. Rules.
21	Photographic Club	"After Treatment of the Negative." Annual Exhibition of Members' Work.
21	Rugby Photographic Society	"The Afterwork of the Picture (Stretching, Mounting, &c.)" Mr. Perrins.
22	Rodley, Farsley, & Calverley Dis.	"Insect Photography." Mr. H. Main, B.Sc.
22	Woolwich Photographic Soc.	"English Royal Heraldry." Mr. G. Davenport, F.S.A.
22	Blenheim Club	Annual Meeting.
22	Harrogate Camera Club	"A Constant Friend: My Camera." Illustrated. Mr. W. A. Taylor.
22	Liverpool Amateur Ph. Assn.	

MEETINGS OF SOCIETIES FOR NEXT WEEK (*Continued*):

March.	Name of Society.	Subject.
12.....	Pudsey and District Photo. Soc.	"Alteration and Improvement of Bromide Enlargements and Prints," Mr. John Way.
12.....	Richmond Camera Club .....	"The Platinotype Process." The Platinotype Company.
12.....	Cardiff Windsor Amat. Ph. Soc.	"In the Llyn Valley," Mr. Woodward.
12.....	Hull Photographic Society .....	Photographic News Prize Slides.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Meeting held March 14, Major-General Waterhouse, President, in the Chair. The Chairman alluded to the loss which the Society had sustained in the death of two of its members, J. J. Vezy and F. Maxwell Lyte. A lecture was then given by Mr. C. P. Butler on the measurement of the composition of celestial bodies, in the course of which the methods of spectro-photometry as applied to the investigation of the sun and the fixed stars were explained and illustrated with a number of lantern-slides. The lecturer dealt at some length with the spectro-photometry of the surface of the sun, and with the investigation of the variations of the sun spots.

**GLOUCESTERSHIRE PHOTOGRAPHIC SOCIETY.**—Mr. S. G. Kimber gave his lecture on "Winchester Cathedral" on the 6th inst., and at the conclusion said that he had made up his mind never to write another such lecture, but, after having seen Gloucester Cathedral that day for the first time, he was greatly tempted to break his word. Cathedral photography was most interesting, and he recommended the members to turn their attention to their own cathedral, where they would find a great deal of good work.

**CROYDON CAMERA CLUB.**—The annual "rummage sale" took place on the 7th inst., Mr. Albright kindly officiating. The occasion always forms a grand opportunity of obtaining a quantity of photographic apparatus at an exceedingly cheap rate, frequently of not the faintest use to the purchaser. On the preceding Wednesday, a demonstration distinctly out of the ordinary, was afforded by Mr. A. J. Newton. In a full consideration of the methods of production of line and process blocks, each step being worked practically, from coating the collodion plate, to the production of the finished block, by one who was obviously a master of a difficult craft. The acrograph celluloid relief system was also shown, and aroused much interest. Some of the points dealt with by Mr. Newton in the course of his lecture, and arising out of the discussion which followed, were of direct utility to photographers, especially to those who at any time might wish to submit photographs for reproduction in the press or magazines. The ideal print for this purpose, said Mr. Newton, was one possessing a black opaque deposit on a pure white background. A glossy bromide print fulfilled these conditions admirably. A matt surfaced paper had a tendency to scatter the light too much. If a silver print was employed for the purpose, then it was of importance that it should not contain a suspicion of double-toning. Half-tone blocks were incapable of reproducing great contrasts, and as the wet plate was to all intents and purposes insensitive to red, a print of that hue would not reproduce well. On the other hand, it was always possible for the block maker to heighten the contrasts of a soft print, if so requested. If a body-colour white were employed for local work, care should be taken not to use Chinese white for the purpose. This absorbs ultra-violet, and therefore does not reproduce faithfully. Blanc D'Argent is cheap and good, but if exposed to light and air, gradually darkens. Winsor and Newton's "Albanine" photographs its true value, and is best for retaining its whiteness. Some of the process whites sold appeared to be Chinese white, merely under another name. The President drew attention to the collodion process for lantern-slides, an old worker in this direction himself. He was aware there were difficulties, but they could be surmounted. Mr. E. A. Salt suggested that amateurs should give the process a trial, if only to meet old wet-plate workers a little on their own ground. The latter frequently adopted an unconscious air of supreme superiority, which was most aggravating. He enquired how the relative cost of dry and wet-plates compared. Mr. J. M. Sellors said he used to assist a friend who worked wet-plates years ago, his share being chiefly confined to cleaning plates and dishes. Judging by the language which used to float round the dark room, the process did not appear to be conducive to moral rectitude. Mr. S. H. Wratten observed that coating a plate evenly and without streaks or ridges, was no easy

matter until the knack was acquired; certainly a quantity of collodion down one's sleeve was trying to the temper. Mr. Newton, in reply, said he agreed with Mr. Wratten that it was a matter of knack, easily acquired by some, but to others difficult. As to the question of cost, even in small sizes the collodion process worked out at about half the cost of the dry plate including labour. Larger sizes would be proportionally cheaper, but against this, unless one could work with wet-plates under ideal conditions, a crop of difficulties in the shape of spots, comets, or fog, might at any time unexpectedly arise. Wet-plates could be finished off, with far greater rapidity than was the case with dry plates, but if both were worked in large batches, then there was not much difference between them in this respect. It was more difficult to obtain good half-tone blocks with the latter, but several large firms used them successfully. Mr. C. E. Kenneth Mees, in proposing a vote of thanks to Mr. Newton, expressed the debt of gratitude the members of the club were under to him for such a pleasant and instructive evening, and in persuasive manner, successfully inveigled the lecturer into promising an exposition on tri-colour process work, in the immediate future.

**BRISTOL PHOTOGRAPHIC CLUB.**—Last week, Mr. F. Little gave a practical demonstration of the making of lantern-slides by contact and by reduction, and showed the method of using masks in combination printing. Mr. Little specially recommended the following developer for obtaining rich black tones with the "Ilford Special" and the "Paget Rapid" lantern plates, viz., amidol, 50 grains; sodium sulphite, 650 grains; potassium bromide, 10 grains; water to 20 ozs.

**SOUTHAMPTON Camera Club.**—The members competed on Monday last in three classes of lantern-slides, portraiture architecture, and other subjects. While the counting was in progress Mr. S. G. Kimber gave an illuminating criticism upon the slides sent in, a departure from ordinary procedure which was much appreciated.

**HEREFORDSHIRE Photographic Society.**—A special meeting was held last week. Mr. Cecil Gethen (the hon. sec.) announced that there was a good prospect of the Photographic Convention of the United Kingdom being held in 1907 in Hereford, and he understood that a formal invitation would be forwarded to the proper quarters by the Mayor and Corporation within the next day or so. On the motion of Mr. Gus. Edwards, seconded by Mr. Ernest Davies, the society resolved to give the visitors, should they select Hereford, a very cordial welcome, and to do all they could to make the gathering a success. Subsequently Mr. Wilfrid Green gave a practical demonstration of enlarging photographs, which was much appreciated by all present. In the Blake Challenge Cup competition, for the best photograph taken during the year, Mr. Harold Baker, F.R.P.S. (the judge), has awarded the cup to Mr. Frank Pritchard, Hereford, for a very pretty sheep study.

**PHOTOGRAPHIC Survey of Surrey.**—The annual meeting of the Photographic Survey and Record of Surrey was held at the Public Library, Kingston-on-Thames, on Saturday, Viscount Mitleton presiding. The report stated that during the year 1905 697 photographs had been received and recorded, against 660 in 1904. The ecclesiastical subjects included a series of wood carvings of the Fifteenth Century from the stalls in the choir at Lingfield Church. Valuable additions had been made to the Archaeological collection, a new feature of which was the application of direct photography to memorial brasses in their normal position. By this means photographs, obtainable previously only through the medium of rubbings, had been added from Stoke d'Abernon and Addington Churches. These had been secured by arranging the camera vertically over the brasses; and it would be possible to use the same method to obtain prints of all Surrey brasses. The Art and Literature section reported that photographs of various interesting documents in the Losley Collection had now been placed in the Town Hall, Croydon. The additions to the Anthropological section included pictures of finds on the site of the old Bermondsey Abbey as well as of important records and objects excavated at the British Camp recently discovered at Carshalton-on-the-Hill. There was also a good series of prints of the pit dwellings on Worm's Heath and one of a scold's bridle, date 1632, kept in the vestry of the church at Walton-on-Thames. To the Natural History section there had been 88 additions, the prints including a charming series of mollusca and insects, and an interesting set of the conifera growing in Kew Gardens.

## Commercial & Legal Intelligence.

**THEFTS** from the Stereoscopic Company.—At the Marlborough Street Police Court, on Saturday, William Stone, shoemaker, with no home, and Frederick Tyler, waiter, with no home, were charged with breaking into the premises of the London Stereoscopic Company, Limited, Regent Street, W., and stealing eight gold lockets and a pendant, of the value of £26. The police constables said that at 5.30 that morning they saw Tyler break the window of the shop with a stone. Both men, it appeared, had served terms of imprisonment, and were committed for trial. The value of the window was about £8.

**THE** Official Receiver for Wandsworth has now issued particulars under the failure of Francis Edwin Ellis, Streatham, London, S.W., from which it appears that the debtor has filed a statement of affairs showing gross liabilities amounting to £1,196 16s. 1d., of which £341 14s. 7d. is due to unsecured creditors. To fully secured creditors £725, the value of the securities being returned at £1,293, thus showing an estimated surplus of £568, which is carried out as an asset. To partly secured creditors £126 14s. 9d., the value of the securities being returned at £80, thus showing a balance of £46 14s. 9d., to rank against the estate for dividend, making the total liabilities amount to £388 9s. 4d. The assets are returned at £618, and include the estimated surplus of £568 from securities in the hands of the fully secured creditors. After deducting the claims of preferential creditors, payable in full, the net assets are returned at £614 13s. 3d., and a surplus of £226 3s. 11d. He accounts for this deficiency by part household expenses of himself, wife, and child since June, 1904, £125. Law costs £336. The Official Receiver states that the creditors treated as fully secured are three, and one of them, the debtor's own solicitors, hold a first charge on the sum of £1,218, due to debtor from the estate of W. Hayward, which debt is secured by a second charge on certain properties belonging to Hayward. The negatives, plant, and stock, which belonged to the late partnership between the debtor and Hayward, are held by the debtor as further security, for the payment of this debt. With regard to the second fully secured creditor, who is the debtor's wife, she holds a second charge on the debt due from Hayward's estate, and the third fully secured creditor, holds as security certain negatives and prints. The partly secured creditors are three in number, and hold respectively a charge on a policy on the debtor's life for £150, a bill of sale over the furniture and effects at "Ivycroft," and certain pawntickets.

**BRITISH** Automatic Photographic Company, Ltd. (London).—A 5 per cent. debenture, dated February 23rd, 1906, to secure £100, charged on the company's property, present and future, including uncalled capital, has been registered. Holders: Burn and Berridge, 11, Old Broad Street, E.C.

### COMPANIES REGISTERED.

**LOCKWOODS** (Chemists), Limited.—Capital, £2,000, in £1 shares. Objects: To acquire the business carried on at 80, Conran Street, and 91, Rochdale Road, Manchester, and at 112, Rochdale Road, 98, Moston Lane, and 233, Conran Street, Harpurhey; and to carry on the business of chemists, druggists, drysalers, dealers in photographic, and scientific appliances and materials, etc. No initial public issue. Registered without articles of association. H. S. Lockwood is the first director. Registered office, 112, Rochdale Road, Harpurhey, Manchester.

**M. W. DUNSCOMBE**, Limited.—Capital, £8,000, in £1 shares. Objects: To acquire the business carried on at 5 and 7, St. Augustine's Parade, Bristol, by M. W. Dunscombe, and to carry on the business of wholesale and retail opticians, photographic, mathematical and scientific instrument manufacturers, etc. No initial public issue. Registered office, 7, St. Augustine's Parade, Bristol.

**COMMERCIAL** Photo Company, Limited.—Capital, £6,000, in £1 shares. To carry on the business of manufacturers of, and dealers in, photographic papers, plates, films, postcards, and mounts, etc. No initial public issue. The number of directors is not to be less than three nor more than five; the first are G. R. Minnikin (managing director, with £200 per annum), R. H. Barker, and G. O. Nicol. Registered office:—Staveley, Westmoreland.

### HALF-DAY CLOSING.

To the Editors.

Gentlemen,—Mr. Lang Sims' advocacy of a half-holiday, to be granted on the same day as the local shop assistants' holiday, is a broad-minded and practical proposal, which is becoming increasingly characteristic of the better class of employers. The smaller and cheaper shops are, I fear, not always inspired with such broad feelings. Long and debilitating hours of service, and an innate dread of granting a fellow-being a few hours of daylight and sunshine for the recreation of muscles and nerves, are largely typical of our second-class establishments.

Is not this short-sighted and wasteful? Does it not defeat its own aim? Does it extract as much labour from the exhausted machine, as would be obtained from an animated and refreshed assistant?

One argues with the poorer class of employer in this strain, and he simply replies: "I cannot afford to work short hours." This can be proved to be wrong, for the chief competitive commercial countries are the short-hour countries (America, England, etc.), not the long-hour ones (Russia, China, Spain, etc.). Long hours, systematically worked, are a proof of bad organisation, nothing more.

And the longer the hours, or smaller the wages, the less productive the workpeople become,—less intelligent,—devoid of initiative and resource, because robbed of hope and ambition, and of their home and open-air amusements, which so build up a man's dignity, and also his physique and nervous tone.

One customary objection to a photographic half-holiday is that the local half-holiday forms the only free time for shop assistants to visit the studio for a sitting. This is not true. Having a close connection with a shop assistants' benevolent society and social club for many years, I found that shop assistants never use their half-holiday for any purposes that curtail amusement or sport. In my business experience of one town, we counted only thirteen shop assistants among our customers on the half-holiday, in the first three years. Then we adopted the half-holiday, and caused those who desired to be photographed on that afternoon to make an appointment. We had only four appointments in the next year, and eventually none at all. It was quite easy to deal with those who were specially placed, and the bulk of people in shop-life find no difficulty in obtaining leave for a sitting, or sitting early.

If photographers in any locality find that any one establishment is an obstacle to the carrying-out of a half-holiday, it may be pointed out that the new Early Closing Act gives the power to two-thirds of a calling in any town to carry the reform and compel the minority to close. There should be no necessity for this, however.

It is necessary to say a few words about general hours, and close my long screed. An advertiser advertises for a really good assistant, say, in these terms:—"Operator and retoucher, thoroughly experienced in posing, lighting, developing, retouching, and with a practical knowledge of turning-out smart work; also beginners, improvers, or amateurs wanted." The first-class applicant finds that in return for this knowledge and smartness he is to be worked from 8.30 a.m. to 7 p.m. daily. Will such a system keep up the level, physically and mentally, of our assistants? Why should the old studio hours of 9 to 6, or 9.30 to 6.30 (with a short interval for tea, and one hour for lunch), be so recklessly broken by numbers of second and third-rate houses, posing as "up-to-date" employers? It is just possible that to produce their type of photographs no great skill or intelligence is required; but in any case it cannot be expected that intelligence will be developed, or ability increased, under such a system. First, the assistants have no time for learning or reading; next, they lose any desire to learn or read, or even to exercise common interest in their daily round. This reflects itself in the produc-

of the studio; it injures the employers' trade, and reduces his profits.—I am, sir, yours respectfully, A MEMBER OF THE P.P.A.  
London, March 12, 1906.

To the Editors.

Gentlemen,—I was very pleased to see Mr. R. Lang Sims' letter in this week's issue of the BRITISH JOURNAL OF PHOTOGRAPHY on the above subject, and trust that other principals will take the matter up and endeavour to make the movement universal. I know many photographers allow their assistants a half day on separate days during the week. This plan, as Mr. Sims says, is at times very inconvenient, and not satisfactory to the young people concerned; it would be more appreciated if all had holiday on the same day. I have been agitating the matter here for some time, with the result that nearly all the leading photographers of Bristol (West) have agreed to close on Saturday afternoons at two o'clock.—Trusting to the aid of many others following this example, I am, dear Sirs, yours faithfully,  
W. H. MIDWINTER.

3, Park Street, Bristol.

March 12, 1906.

Several other letters on this subject which reach us as we go to press must stand over until next week.—Eds., B.J.P.]

#### A COLOUR-PHOTOGRAPHY SOCIETY.

To the Editors.

Gentlemen,—The suggestion made by Mr. Howard Farmer, in his letter, published in the current issue of the B.J.P., is one which does not necessarily appeal to those whose work in colour-photography has made the present exhibition so representative of the stage to which it has advanced. The present exhibitors must feel that their efforts to-day are but a phase in an art growing so rapidly that these efforts mark a great advance on the achievements of but a few years

ago. The stages of growth of an art are with difficulty traced when it reaches its full development, and it is because the exhibition of B.J.P. marks a stage in the early promise of colour-photography that the suggestion of Mr. Howard Farmer strikes me as valuable. As an exhibitor, I may say that should any or all of my efforts be considered of sufficient interest I should be most happy to present them with a view to the preservation intact of the present collection.

It has been further suggested that this first Exhibition of Triumphant Photography might well be the precursor of periodic exhibitions of a similar character, and that the occasional meeting of workers in this branch of the art could not fail to advance our knowledge of the ways of overcoming the many difficulties with which it is still beset.

The Editors of the B.J.P. have succeeded so well in bringing before the public the samples of the work that it occurs to me that they might further their efforts by convening a meeting of the workers themselves with a view to the formation of a Society of Workers in Colour-Photography. I will, at least, so far trespass on your courtesy, Gentlemen, as to throw out the suggestion.—Yours faithfully,  
EDWIN T. BUTLER.

Craven Park, Willesden, N.W., March 10, 1906.

We shall be prepared to further Mr. Butler's timely suggestion by using our columns to the views of those interested as to the form which such a society should take. It seems to us that the progress of individual workers would be aided by a circulating portfolio of specimens, and by the establishment of a register of the names and addresses of members in a position to correspond with others on technical difficulties. Perhaps those in favour of the formation of a body will communicate with us when we will consider what may be taken.—Eds. B.J.P.]

#### THE PHOTOTYPE COMPANY, LIMITED.

To the Editors.

Gentlemen,—To prevent any misunderstanding reflecting on the policy of the above company by the report of my private affairs, I wish to inform you that such proceedings do not concern the Phototype Company in any way, and that we have always made it a policy in our business to pay cash for everything where possible, and to benefit by the fullest cash discounts offered by the trade,

thereby enabling us to give our customers the best value for money. I can say that at no time (after the 15th of each month), have our liabilities ever exceeded £20. This principle will be carried out to the letter as long as I have anything to do with the company. Our share capital is £2,000, of which only £706 15s. is called up.—Yours faithfully,  
F. CRICHTON-TEMPLE, Secretary.

London Office, 221, Temple Chambers, E.C.,

March, 9, 1906.

#### SULPHIDE TONING.

To the Editors.

Gentlemen,—Your interesting notes on the subject of sulphide toning, under the heading of "Ex Cathedra," in your recent issue, are suggestive of some comment.

It is stated that the facts detailed in these notes "do not in any way disprove the existence of silver monosulphide in the brown toned image." In other words, the results obtained are only not inconsistent with the toned deposit being silver monosulphide. But are there any strong grounds for believing the toned deposit to consist of pure silver monosulphide? May it not more probably be a complex sulphur, containing compound of silver? If colour be regarded as any clue to identity, appearances are certainly against the view that the deposit is ordinary silver sulphide, for the red-brown colour of toned prints contrasts strongly with the rich black of ordinarily prepared  $Ag_2S$ .

Of course, such a difference in colour in the two cases might be ascribed to a dichroism, analogous to that shown by such substances as blood or  $CuSO_4$  solution, when layers of varying thicknesses of these substances are examined.

But a fact mentioned in the notes suggests more forcibly another view of the matter. It is stated that cyanogen compounds, removable by treatment with dilute acids, remain in the prints after they have undergone a considerable amount of washing. It is inferred that these cyanogen compounds are soluble, else the recommendation to wash longer than is usually the custom is meaningless. But may not the cyanogen compound be in the deposit in insoluble combination, and not, as implied, in the paper in a soluble condition? It is a fact well known to analysts that the presence of complex cyanogen containing acid radicles (such as  $Fe_3(CN)_6$ ), so greatly interferes with the usual course of analysis (based mainly on sulphide separations) that it is customary to make a preliminary test for such radicles, and if found to destroy them before proceeding to the systematic analysis. The capacity which sulphides have of forming what, for lack of more precise knowledge, we call "molecular compounds," is well known. The "magpie precipitate" thrown down from mercuric salts by  $H_2S$  may be instanced, as also the brilliant red compound sometimes precipitated by the same reagent from bismuth solutions in place of the pure brown sulphide.

From the point of view of these comments the question suggests itself: Is the potassium bromide prescribed in the bleaching solution for sulphide toning absolutely essential to the process? If so, what exactly is its function, other than perhaps an accelerative one? I ask this question with some trepidation. Unfortunately, I am not at present in the position to answer it for myself by direct appeal to the tribunal of experiment.—Yours faithfully,

DOUGLAS CARNEGIE.

Newton Abbot.

[An alkaline solution of ferricyanide without bromide, as our correspondent doubtless knows, will serve as a bleaching solution, and even a neutral ferricyanide solution, if it is given plenty of time to act, will bleach, though not to a complete stage. The bromide is thus not essential to the operation, though we have not any quantitative data to tell us what part it takes in the reaction. Our notes were written to show that there are chemical reasons for distrusting a ferricyanide bleacher as regards future immunity from stains. In practice we believe ferricyanide plus bromide is the most popular, and is the basis of several commercial preparations. Yet, as our experiments have shown, and, as Mr. Carnegie states, the formation of complex cyanogen compounds may be an unfavourable characteristic of it. Chemically, a solution of bromine is a bleaching solution, which cannot be improved upon, and is altogether excellent in the colour and depth of the results. Its one defect is the irritating vapour.—Eds. B.J.P.]

## Answers to Correspondents.

- \*<sup>a</sup> All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \*<sup>a</sup> Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*<sup>a</sup> Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \*<sup>a</sup> For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- W. Harrison, 68, Meadow Road, Leeds. *Photograph of the Hunslet Cricket Club, 1905.*
- W. Brown, 9, Gilmour Street, Paisley, Scotland. *Photograph of the Rev. James Marr, B.D.*
- W. Harrison, Holly Bank, Onchan, Isle-of-Man. *Photograph of the Steamship "Viking," leaving Douglas.*
- H. A. Aylward, 17, Wote Street, Basingstoke. *Photograph of the late James Neillie, Esq. Photograph of Mr. Clavell Suter, K.C.*
- L. F. J. Hawsels, 27, Topsheld Parade, Crouch End, London, N. *Photograph of the Rev. J. B. McHarry.*
- J. E. Miller, 40, Seorton Street, Liverpool, Lancashire. *Photograph of a Group of Boulders with Prizes.*
- Art. Printers, Ltd., Counterslip, Bristol. *Photograph (Combination) entitled, Free Trade v. Fair Trade.*

TONING, ETC.—Will you please give through your correspondence column in the JOURNAL:—1. A formula for toning matt collodion paper to sepia or red tones? I believe it is done with chalk, but do not know exact proportion. 2. Also a developer suitable for intensified negatives, previously bleached with mercury.—D.

1. The formula required is probably that suggested by Kessler (see B.J. Almanac, p. 811). Chalk, 125 grains; water, 10 ozs.; chloride of gold,  $\frac{1}{2}$  grain. Allow to stand for two hours and use the clear solution. The thiocarbamide bath also given on the same page may be used with excellent results. 2. Almost any developer may be used for the development of negatives bleached with mercury. If but slight intensification is required then ferrous oxalate should be used; but an alkaline developer, such as metol-hydroquinone, or adurol, containing sulphite, will give greater increase of density.

D. MACBETH.—Prints on your paper would be as permanent as those on any other printing-out paper.

Brompton.—We presume it is a telephoto lens, and the separation of negative and positive would also be altered. That is so in the case of the "adjustable landscape lens." The same principle could be applied to an R.R., placing a negative lens behind, but the exposures would, of course, be lengthened in proportion to the magnification.

STUDIO QUERY.—I am thinking of building a studio 26 ft. x 12 ft. inside. To get the width I shall have to come close to a 4 ft. 6 in. wall, therefore I thought it would be more convenient for repairing, etc., if I had a single slope roof at an angle of 60 degs. My sitters abhor a dark shadow side of face. With this type of studio can I avoid that without using a reflector, which is rather unsatisfactory when taking groups, as it has little effect on those in the centre of same, and a nuisance when you have a rush of sitters? I thought of 8 ft. eaves, and 5 ft. respectively; glass, 16 ft. square; angle, 60 degs. Does this type of studio do well for wedding and other groups, or is the 5 ft. side liable to unduly interfere? If you will kindly let me know your opinion I shall esteem it a favour, as I do not want to spend money in vain.—UP-TO-DATE.

Of the two designs we should give preference to that shown in No. 2, with the glass as marked by the dotted line. There will

be no difficulty about unduly dark shadows if the blank side is papered, or painted, in a light tint. The studio will answer well for groups, as also for single figures. In such a studio you should get excellent pictures.

BENEFIT SOCIETY.—Could you kindly inform me whether there is any benefit society existing for photographers' assistants?—BYRON.

None, we believe.

A. K.—We would advise you to use the formula directed by the makers of the paper, or, in the event of there being none, the following: 1. Hypo, 12 ozs., dissolved in water, and made up to two pints. 2. Ammonium sulphocyanide,  $\frac{1}{2}$  oz.; water, 5 ozs. 3. Lead acetate,  $\frac{1}{2}$  oz.; water, 5 ozs. 4. Gold chloride, 15 grains; water, 5 ozs. Take of No. 1, 7 ozs.; of No. 2, 1 oz.; of No. 3, 1 oz.; and of No. 4,  $\frac{1}{2}$  oz.

E. N. (Wigan).—Probably the negatives are not vigorous enough. Try developing them longer and printing on a bromide or gaslight paper. Why do you not send us prints, showing the defect complained of.

ARTISTIC LENSES.—Would you object to stating if the lenses (including the single one) discussed in last week's B.J., could easily be used for both landscape and portraiture work? Which is the best "all-round" lens? What would be the effect of using the landscape lens for portraiture, and vice versa?—IGNORANT.

The "adjustable landscape lens" is described by Major Pyndar as suitable also for portraiture, but the special portrait series of anachromatic lenses work at larger apertures. Probably the "adjustable landscape" is the best all-round lens of the anachromatic.

SUSSEX.—We know of no obstacle. Many reputable photographers do so.

COPYING.—Is there any simple contrivance by which an object about half-inch in length could be photographed twice natural size?—X. Y. Z.

Certainly; photograph it in the ordinary way, placing it at distance from the lens equal to one and half times the focal length of lens. The camera extension will be three times the focal length.

MOGGLETONE.—You have no remedy for infringement before registration. We should advise you, however, to draw the facts of the copy having appeared on the paper to the attention of the proprietors, and ask them what they propose doing.

HOLIDAY.—Under the circumstances, absence of any written understanding, we do not see how you can claim the holiday. Certainly you cannot claim the salary in lieu of it.

ENLARGEMENTS.—Could you kindly give me particulars of the process and apparatus required to produce solar pictures and enlargements?—SOLAR.

We have answered this question several times lately, and given full formulæ in our issue of May 19 last year. The paper is saturated with a mixture of iodides, bromides and chlorides, and sensitized by floating on silver nitrate solution. A developer of gallic acid is then applied.

\*<sup>a</sup> NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Impressionism, which is the modern fashion in Art, stops short at where difficulty begins. . . . Its facility of execution is necessarily effective, decoratively, and a certain number of imitators, captivated by its facility and novelty, are following the lead given. . . . mistaking a part for the whole." This view of modern Art expressed by Mr. J. C. Dollman in a paper on "Art in Painting and Photography." (P. 225.)

A Bill is being brought before Parliament to make the adoption of the metric system compulsory. (P. 222.)

The precaution of a full trial is recommended to purchasers of new apparatus. (P. 223.)

For local and general intensification of negatives the "powder" process might be more generally used for its inability to damage the negative and its power of localising effects. (P. 223.)

For retouching negatives of interior subjects, Mr. Arthur Whiting, a combination of rubbing down and knifing the film, and cutting the glass side. (P. 225.)

Several correspondents support the recent suggestion of a half-day closing for photographers. (P. 225.)

A second case has come up in which a photographer has successfully resisted a summons from a local surveyor classing a wooden box-case as a "building." (P. 235.)

## EX CATHEDRA.

### The Exhibition of Colour Photography.

Several other exhibitors of colour-photographs having signified their approval of Mr. Howard Farmer's suggestion of a permanent collection, we have approached the Royal Photographic Society, as the body best able to find proper accommodation for such a collection, and we are in a position to report that in a letter from the Secretary, authorised by the Council, the Society accepts our proposal that it should provide wall space for prints and means of displaying the transparencies which have formed the recent exhibition. Our intention, therefore, so far as authorisation from our exhibitors empowers us, is to hand over the exhibits to the Royal Photographic Society, by whom their receipt will be acknowledged to each individual donor.

\* \* \*

### Another Photographic Exhibition in Paris.

We learn from a circular of the "Photo-Touring de France" that it is arranging its first annual international exhibition of photography for June 6 to 17, in the Serres de la Ville de Paris, near the Champs Elysées. The "Photo-Touring," we understand, is a young body, scarcely a year old, and its officers appear to be drawn in a number of cases from the staff of a journal called "Photo Pêle-Mêle," of 106, Rue de Richelieu, from which address the affairs of the proposed exhibition are to be administered. The charge for each picture exhibited is 2 francs, or for societies exhibiting *en bloc*, 10 francs. The aim of the "Photo-Touring," it is stated, is purely artistic, but the exhibition is being given a somewhat wider character, and exhibits of apparatus and accessories—in short, the trade—will be admitted. We confess we should like to know more of the "Photo-Touring," which, presumably, has nothing to do with the "Association des Amateurs Photographes du Touring-Club," of which M. F. Lagrange is the secretary, and of which M. Lippmann is an honorary president. Yet the scheme of the proposed exhibition appears to be one which it should be easy to carry out successfully.

\* \* \*

### Lenses Old and New.

Those who have only recently taken up photography have little idea of the advantages they possess over the much less fortunate individuals who began their experience some few years back. A short time ago we had the opportunity of looking over a stock of old lenses, and of borrowing some of them for experimental purposes. Among them was one of the "rapid rectilinear" hand camera lenses that were on the market something like twelve years ago to meet the demand for very rapid lenses suitable for snapshot work. This lens was of 6 inches focal length, and was supposed to cover a quarter-plate at *f*/5.6. We tried it carefully, and found that it would not cover that size plate with decent definition at *f*/8, while at *f*/11 its performance left

much to be desired. Out of curiosity we looked up the price of this lens in an old "Almanac," and found it was listed at £5! Only a few weeks previously we had been testing some modern cheap five-inch rectilinears working at  $f/8$  and costing about 30s. We found that their quality was variable, but they were all better than the old six-inch lens, and at least one of them was a distinctly good specimen that covered a quarter-plate sharply to the corners at  $f/8$ . This lens was well worth its cost, while the old one would be a bad bargain at half-a-crown, though it would certainly fetch much more than that at a sale, by virtue of the name of its maker. The modern photographer can obtain an anastigmat of the very highest quality for the original price of that old R.R. lens, while he can get a lens that is probably as good as he needs for less than a third the price. High-priced R.R. lenses of very moderate efficiency were by no means uncommon some few years ago, and it now seems curious that they should have even commanded a sale, considering that the same lists that mention them also include very good anastigmats at about the same price.

\* \* \*

#### **Collodion v. Gelatine Plates for Lantern Slides.**

At a recent meeting of the Croydon Camera Club there was an interesting discussion on the wet collodion process—one of the members suggesting that amateurs should give it a trial for lantern slides. During the discussion one of the chief difficulties in working the process seemed to be looked upon as the coating of the plate evenly with the collodion. Most workers of the process—and those who have taught it to others—would look upon the cleaning of the glass before it is coated as a far greater difficulty to the beginner than coating the plate after it is cleaned. Those who are only familiar with the working of gelatine plates have no conception of the extreme chemical cleanliness necessary at the initial as at every later stage of the wet collodion process. Compared with these the coating of the plate is a mere bagatelle, especially when only small plates are in question. In the old days amateurs used to work the collodion process successfully, and the favourite sizes with them then were the seven and half by five and the ten by eight inches, and after a very little practice they were able to coat the plates evenly, even when working away from home in small and ill-ventilated tents. If this were the case then, and under trying conditions, we see no reason why amateurs of the present day should be debarred from trying the collodion process for such small sizes as lantern slides by reason of the alleged difficulties in coating the plates. Large commercial carbon enlargements are printed from collodion negatives, and these are sometimes four feet by three, and larger, yet the plates are evenly coated, and in precisely the same way as smaller ones. That the collodion process is an admirable one for the production of lantern slides is evidenced by the fact that so large a proportion of the commercial slides are by that process. But, seeing the excellence of the gelatine lantern plates now on the market, and the ease with which good results may be obtained with them, we imagine that few will take up the collodion process solely for lantern-slide work.

\* \* \*

#### **The Metric System.**

It is announced that, at the instance of the Decimal Association, Mr. Henry Norman is about to introduce a Bill in the House of Commons for the compulsory adoption of the metric system of weights and measures in Great Britain. Writing to the daily press, one day last week, the secretary of that Association said that he has received fifty-three promises of support from newly-elected M.P.'s. It appears that in the last

Parliament there were 330 members pledged to support the adoption of the metric weights and measures in this country, that at the present time 253 votes can be relied upon in the House of Commons, and that additional assents are being received day by day. It is probable that when the canvass now proceeding is completed that there will be many supporters in the present Parliament as there were in the last. We must wait to see the fate the bill will meet with, if time is found for its discussion. Whatever that may be there is no question that the universal adoption of the metric system would be a great convenience to photographers. Great Britain is about the only European country in which the metric system is not the one in universal use, and it has more than once been suggested in these columns that, without waiting for the compulsory adoption of the metric system in this country, it should be universally adopted amongst photographers. Some years ago the "Photographic Club" made strenuous efforts to get photographers to take it up, but nothing practically came of it. Most of our plates and paper makers now give the formulae for their developers both under the English and the metric systems, but few, we imagine, in this country make them up according to the latter. Perhaps one reason why the metric system has not been more generally taken up by photographers may be that metric weights and measures are not stocked by photographic dealers. We have before us the full catalogues of two of the largest London houses, and in neither of them are metric weights and measures mentioned.

\* \* \*

#### **Inducements to Purchase.**

We have commented in these columns before on the wisdom of putting quality before cheapness as a means of drawing customers to a studio. Photographic portraits being a luxury, the inducement of a low price is not the essential factor it is in the sale of necessities of life. We were reminded of the weakness of the "price" inducement recently on visiting a photographic exhibition where a professional photographer was occupying space for which, we suppose, he had paid like any other exhibitor outside the regular classes. And the only use he was able to make of the occasion was to advertise the meaningless offer that on all orders received at the exhibition he would allow a discount of 25 per cent. We cannot imagine that the difference between 12s. and 9s., unaccompanied by any plausible reason for it, would lead persons to place their orders. We should have thought that more was to be gained by a careful display of a little of the photographer's best work, presented in a way which should appeal to people who, by their presence at such an exhibition, might be credited with a certain degree of taste in photographic matters.

\* \* \*

#### **Enlargements as a Means of Pushing Business.**

We have frequently pointed out in these pages the necessity for seeking business rather than sitting down and waiting for it. It is an undoubted fact that there are many people with money to spend who merely need the direction to be indicated. The shop window displays are far more likely to catch the eye of those who do not know what they want than to guide the buyer who starts out with a definite intention. This, of course, applies particularly to businesses supplying luxuries, such as photographs undoubtedly are, in the majority of cases. The late H. P. Robinson pointed out years ago that more might have been done with ceramic enamels had photographers supplying them devoted some ingenuity to applying them in other directions than to brooches and special morocco cases. We do not think as much business is got out of enlargements as might be. The expense of a number of specula-

enlargements is perhaps a consideration, though such  
ires, enlarged and finished in very effective styles, are  
e had at remarkably low prices. We may suggest,  
ever, that a simple form of day or artificial light en-  
ber be fitted in the premises, and then at a cost of about  
once an enlargement can be made, rough mounted, and  
ed in a stock frame so that it may be shown to the  
omer under favourable conditions. Artificial light  
d have the advantage of allowing such work to be done  
e evening when studio sittings or daylight printing  
over for the day.

# **Chasing aratus.**

The time of the year being at hand when  
many of our readers will be purchasing  
new apparatus for use during the forth-  
ing season, a hint on one point may be permitted. It  
at first sight, appear superfluous if the apparatus be  
ht from a high-class house, yet slight errors may, at  
s, occur in the best regulated workshops, and not be  
ted even when the apparatus is carefully examined  
e it is sold. It is only when the purchaser uses it  
ne field that its shortcomings, if any, are discovered,  
not then until, perhaps, the whole of a holiday's work  
und worthless. We may instance two or three cases  
h have come before us. A camera of the twin-lens  
was ordered from one of the most noted makers. A  
of lenses were also ordered for it from a well-known  
on house by the customer. The camera-maker in due  
e fitted them to the apparatus, and it was then, with-  
rrial, taken on a tour abroad, and many dozen plates  
sed. These, when developed, proved to be all more  
s out of focus; some, those exposed with the full  
ing of the lens, hopelessly so. The maker of the  
ra was blamed for his work, but he protested that the  
r and the plate were in accurate register, and so they  
The lenses were then put on to a bi-lens camera, and  
as at once seen that there was a difference in their  
although they were supposed to be accurately paired.  
a few plates been exposed in the apparatus before it  
taken abroad the error would have been detected,  
disappointment and annoyance avoided.

# **Rehearsed periences.**

Another case:—An experienced amateur  
photographer, passing through London  
ute to a far off country, purchased a hand camera of  
eflex type of a well-known house, and took it away  
him direct, without trial. Several dozen plates and  
were exposed on the tour, and when they were  
oped it was found that they were all more or less  
d, the longest exposure the most so. The apparatus  
hen put into the hands of an expert, who found that  
of light gained access to the plate by the side of the  
r when it was in a certain position during the ex-  
e. The defect was easily remedied, but the photo-  
ic results of a far away holiday tour were more or less  
. Had the apparatus, before being taken away, been  
a few times out of doors, the defect would have been  
ced and quickly set right. Not long ago, in a con-  
ary, a photographer detailed some of his grievances  
st apparatus manufacturers, and mentioned that he  
ought a new camera, and took it out to do some work,  
hen found that he could not draw any of the shutters  
slides, and had to go home without making an ex-  
e. It is a little difficult to imagine that any photo-  
er, particularly a professional, should go with a new  
atus into a field without taking the precaution to see if  
utters of the slides could be drawn, but such appears  
been the case. However, as the above cases serve to

illustrate that errors sometimes occur even in the work-  
shops of the best houses, although they are not frequent,  
yet when they do occur, they usually cause very considerable  
annoyance. Seeing the possibilities of such things happen-  
ing, we strongly advise all purchasers of new apparatus  
not to go away on a tour with it without previously having  
a full dress rehearsal in the field under the most trying  
conditions.

## **Local Intensification of Negatives.**

It is sometimes desirable to intensify  
certain portions of a negative while other  
parts are retained in their original state.  
Various methods of local intensification have, at different  
times, been published, and most answer well in the hands  
of those familiar with the working of them. But in the  
hands of novices they have sometimes led to the ruin of a  
valued negative. The powder, or, as it is sometimes called,  
the dusting-on, process lends itself well to the local intensi-  
fication of negatives, and, though it has more than once  
been advocated for the purpose, it is but little used. It is  
simple to work, and with it there is no risk whatever of  
injury to the negative. Again, if the result first produced  
is not altogether satisfactory, the work can be cleaned off  
and commenced afresh without the slightest fear of  
damage to the negative, as the intensification is done on  
the back of it. There are various formulae for the dusting-  
on process, and that given on page 986 of the "Almanac"  
is as good as any. It stands thus:—

Gum arabic .....	80 grains.
White sugar .....	60 grains.
Ammonium bichromate .....	60 grains.
Water .....	7 ounces.
Methylated spirit .....	1 ounce.

A thin coating of this is spread upon a glass plate and  
dried before the fire, or over a spirit lamp, in a darkened  
room, and then allowed to rest for a while after it is cold.  
If a dry powder is dusted over the plate in this state the  
powder will adhere evenly all over. But if the plate be  
exposed to light, under a negative, the powder will only  
adhere where it has been more or less protected from the  
action of light. In intensifying a negative the powder  
process is used as follows:—Some of the above mixture is  
flowed over the glass side of the negative and drained off.  
The plate is then held before the fire until it is dry, and,  
while still warm, is laid, picture side upward, on a piece  
of black velvet, or cloth, and exposed to diffused light for  
a few minutes. It is then taken into the room, and some  
finely-powdered plumbago is applied with a soft camel-hair  
brush. It will be found to adhere in proportion as the  
film has been protected by the image of the negative, and,  
where the light has fully acted, it will not adhere at all.  
This being the case, it is obvious that if the powder be  
applied locally, only those portions will be strengthened,  
while the others will be left intact. In this way we have  
ample scope for individual treatment. Should the work  
not prove satisfactory the film can be cleaned off with a  
damp cloth and a fresh coating applied as before. If the  
powder takes too freely it is a sign that there is too much  
moisture in the film, and the plate should be slightly  
warmed again. If, on the other hand, it does not take  
freely enough the plate may be lightly breathed upon.  
The simplest way of fixing the powder image is to expose  
it, film side, to light for half an hour or so to harden the  
film. The slight tint of the bichromate will but very  
slightly retard the printing, and, therefore, need not be  
removed. It may be mentioned that but very little of the  
plumbago is necessary on the film, as it has great intensify-  
ing power.

## THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATIONS OF ENGLAND AND AMERICA.

IN our last week's issue we gave the annual report of the Professional Photographers' Association, and, following it, some account of the doings of the Professional Photographers' Society of New York, and the two, taken together, are interesting as well as instructive, since both institutions have the same common object in view—namely, the mutual benefit of their members. From what we gather from the reports of the meetings of the American Society, several of which have from time to time been published in our pages, there would seem to be a greater *entente cordiale* existing amongst professional photographers in the States than is the case in this country. Americans seem willing and anxious to assist their brethren in their business methods, and so raise the status of the profession generally. Early next month there is to be a two days' meeting and exhibition in New York. As described by the President of the Society, "it will be an 'at home' affair. The talks will concern 'the business,' the pictures will be 'business pictures,' and everybody that attends will be just 'business folks.'" This reads as a very business-like circular, and we have little doubt, from what we know of American professional photographers, that the meeting will prove beneficial to all the members. It will doubtless occur to some that a similar exhibition in this country, under the auspices of the P.P.A., would be desirable, if run on purely business lines—more especially as technical

photography is not at all well represented at the different exhibitions. There is no question that the P.P.A. is necessary, that it is doing good work, and that it would do more if it received better support from the profession generally. The annual report shows that between fifty and sixty new members have joined, while some twenty members have been lost by death or resignation. But the most unsatisfactory intimation is that the names of about sixty members will have to be removed because repeated applications have failed to produce payment of the subscription. This is not at all to the credit of these persons, seeing that the subscription to the P.P.A. is only 5s. We are frequently appealed to, as shown by the "Answers" column for advice on business matters, trade disputes, quality of goods supplied, disputed accounts, non-executed orders, copyright, etc. Yet it frequently happens that it is impossible or inadvisable to reply fully to such questions in print, and we have often had occasion to refer querists or disputants to the P.P.A.

Surely no one is in a better position to arbitrate in trade disputes than a body of professional photographers of standing, and for its services in this direction alone the P.P.A. deserves the widest support from the photographic profession. Over and over again it has been the means of avoiding more or less costly law proceedings to the mutual satisfaction of all parties concerned, and we would omit no opportunity of impressing upon photographers the intimate relations which should exist between themselves and the Association which in many ways has justified its claims to advance the status of photography as a calling.

## RETOUCHING NEGATIVES OF INTERIORS.

It is a pity that negatives of interiors so rarely pass through the hands of the retoucher, for it is a fact that, however perfect a negative may be, it rarely happens that it cannot be improved technically by judicious hand-work. And if, on the other hand (as is sometimes the case), it is of such poor quality as to be considered a failure, then skilful manipulation with the pencil and its allies may atone for its faults and make it more or less presentable. I once knew a gigantic order for photographs of a Royal function (interior) to be lost because the negatives were too bad to use, and although the firm was one of good standing, it was ignorant of the fact that they could be made presentable. I afterwards retouched these negatives, and gained thereby the acknowledgment that the order could have been retained had the work been done at the time.

Speaking generally, faulty negatives of interiors give either a harsh black and white chalky appearance, with plenty of halation, or else a flat hazy effect from over-exposure. Doubtless the difficulty of correctly judging the exposure, together with the use of unbacked plates, is answerable for the majority of failures, but, thanks to the craft of the negative-artist, these unpleasantnesses may be practically annihilated.

### Removing Halation.

First let us consider how to make that white patch of halo occupying the place of a window represent the beautiful stained glass pictures which should be there. No doubt all are acquainted with the process known as "rubbing down," and some also will remember the patch-like effects they have occasionally produced by its aid. To tell the truth, rubbing down halation from the top of a few trees requires much less skill than removing halos from stained glass windows, for

you have not only to take away those "sun-dogs" and blot the printing density of the window down to that of the rest of the negative, but also to preserve the delicate detail of pictures and lattices, as well as the representation of architecture at each side. And the work must be done with strict sense of delimitation.

The materials used are cotton wool, the finest tripoli powder and alcohol. Methylated spirit is generally employed, and have tried many others, such as benzine, benzole, chloroform, ether, etc.; and also "Globe" polish, tripoli with indiarubber, methylated spirit alone, flour of emery, and other mechanical reducers, but must give the palm to tripoli and absolute (or methylated) alcohol. The latter is difficult to obtain, and expensive, but by far preferable.

Apply the mixture evenly, gently, and confine the friction strictly to the part to be reduced. When of a proper density wipe off with methylated spirit, and if the appearance is then satisfactory (excepting a few shadow lines), attention must be paid to reducing masses of masonry, reflection from glass of picture-frame, or aught else that will print out too white. Such parts can be likewise reduced if they consist of large patches, but if small, or of narrow proportions, the retouching knife will be a more convenient instrument to use. Occasionally the tripoli-and-alcohol method is useful in such places, if applied on a piece of cotton wool or surgeon's pad previously bound over the end of a flat wedge-pointed stick.

### Knifing in Local Reduction.

For clearing away the clogging in the fine shadow lines and detail in windows, sculpture, and masonry, a knife different from the usual scalpel pattern is of service. It is made from a drill (No. 12 to 15) or a carpet needle. If the

latter, break off the eye, soften the steel in a fire or t-flame, and then file off to a chisel-shaped edge, one side of thus being bevelled and the other flat. The edge will not be square (horizontal) to the length of the needle, the left-hand end (viewed from the flat side) should lie a little obliquely. After it has been shaped, make hot, and plunge immediately into cold water to harden steel. When the pointed end has been placed in a handle, the shaped edge can be sharpened on an oil-stone. A fine argument of this description enables the artist to locate work more easily than a scalpel will do, and thus to act ditiously.

#### Matting the Negative for Retouching.

When all the dark detail and shadows have been efficiently t with, cover the negative with medium all over, and t up the light detail of the parts rubbed down. Next tish the negative with "matting" varnish and rub down rule 1, 2 or 5, page 960-1, in this year's "B.J. Almanac," answer for a recipe). If the negative is valuable, or a number of prints are to be made, it will be safer to ionize the negative previously, to prevent staining, as varnishes like the above do not protect as well as the l hard negative varieties. In any case, when the varnish

is matted, work over the little inequalities of depth (caused by rubbing down the film) with a stump and plumbago; also lighten all broad shadows likely to print too heavily by the same means, or, if the surface is very great, use a tint stump instead. After they have received correction, work up the lighter detail and higher half-tones, and lights, including the work on friezes, screens, statuary, etc., with lead pencil, until they seem to stand out somewhat stereoscopically, for, generally speaking—of course, there are exceptions—brilliancy with softness of tone and excellency of definition are aimed at in making photographs of interiors. When the pencilling is completed, you will probably have drawn a perfect picture of the interior on the surface of the varnish, which may be seen by holding the negative horizontally. It may be as well to mention that the pencil will not need such a fine point as is necessary for portrait retouching; an ordinary point as used for drawing purposes is better.

During the dull days, whilst the retouchers are slack, they might well fill up their time by working up stock negatives of interiors of churches, chapels, and other buildings, for which there is a ready sale; and assuredly, if the work is well done, after copies will appear to have been made from a better and brighter batch of negatives altogether.

ARTHUR WHITING.

## ART IN PAINTING AND PHOTOGRAPHY.

(A paper read before the Society of Arts on March 7.)

short time ago I received a newspaper cutting from a friend of , who knew I was to have the pleasure of addressing you this ng on the subjects of painting and photography. The paragraph tained was evidently part of a correspondence being conducted a paper on what were considered to be the rival claims of paint- and photography as the exponents of art. The discussion appar- had taken the turn of weighing the claims of the two exponents, figured in the letter under the title of "The Man with a Con- on" and "The Camera Man." As the argument progressed, and oros and cons were given, one read of the ultimate triumph of e Camera Man" and of the eventual downfall to ignominy of e Man with a Conception" who would, no doubt, it was politely ated, "finally disappear."

ference to a matter of comparatively such small importance as etter, may appear to be slight foundation for a paper concerning ument, but there is, unfortunately, a good deal being said and ed of a like nature in connection with it; which is only of a eef-breeding, character, that can be for no good, and frequently s men of repute into an idle argument which they presently t having embarked upon. Now I submit that all such discussions e relevant, and are but a waste of time, for it is foolish to spend y in disputing who is going to do a thing best while the time so yed might be given to the subject itself. The study of art is the t of both fraternities, and whether the man devoted to that t elects to work with the palette, or the camera, he must remem- that he is engaged upon the study of a serious and beautiful sub- and realise the fact that its followers have far more to gain by ng in unity than they could ever achieve by disputing on the

If the art of futurity is to be produced by the camera, well and t let us be thankful to know that the future will contain art, t if such be the case, that the camera be the instrument of it, it t still require to be handled by a man with conception, for, as we t, art is found only in the personality of the individual and does t depend upon any special apparatus. In the meantime let all tvers of art assist each other, for it is a profession which enjoys t dignity of standing by itself, in this kingdom, without assistance, t with not too much of encouragement, for the spirit of the age is a tercial one, and the public moneys are utilised by the State for t construction of huge engines of war for the protection and develop-

ment of this spirit, leaving the gentler arts of peace to shift for themselves.

#### Schools in Art.

Art itself at the present day, or, perhaps, rather pictorial art, is in a somewhat eruptive condition, and it might be advantageous for us to give a short time to its consideration. Periodically, for all time, the art of painting has been subject to the vigorous action taken by groups of strong men who have felt called upon to assert their independent views, and to act in concert in supporting them. These groups of men have always been so vital in their work, and have so tenaciously adhered to their aims, that in course of time they attain to the dignity of being entitled "schools." The particular individuality of each of these schools is always associated with the emphatic insistence upon one or other of the canons of art at the expense of the remainder. Either forcible dwelling upon the quality of detail alone, or tone, colour, light and shade, or general effect. There are those among us who can remember the appearance of schools affecting all these features, back to the "Pre-Raphaelite" body, whose passion was excessive detail. These movements are generally well timed, and indeed may be considered to be the natural outcome of their age, the calling attention to some weak point in the art of the period; and, even if, in the enthusiasm of the quest, its votaries outstrip the bounds of moderation, the gain to the common cause is great.

#### Form is the Essence of Art.

The movement of the present day we are all familiar with, under the title of "Impressionism." Impressionism differs from the schools that have preceded it in the fact that it makes no effort in the direction of adding to the existing practice of painting. On the contrary, it subtracts a good deal from it. It contents itself with a memorandum of the effect, and avoids the risk of contending with other qualities. The principal notes are struck, and left, without any gradation or attempt at delicacy or detail, the resulting effort, regarded as a picture, stops short just where difficulty begins—that of showing knowledge and management in the more subtle passages of the painter's art. The canvases are really beginnings of pictures, left in the state which has been known from all time among painters as the "laying in" stage. The facility of execution which this class of work offers the painter is necessarily effective, decoratively; and a certain number of imitators, captivated by its facility and novelty,

are following the lead given, as other men have followed other leads—mistaking a part for the whole, and they will have the misfortune of leaving no art legacy behind them. But the sobering influence of time in all these cases is the healer, and though, in the course of nature, the dying out of the school of the day makes room for that of the next, the good which is found in them is duly gathered by, and incorporated into, the beautiful things we know as art. So those of us who aspire to know of art, in its larger sense, must put ourselves outside the influences of these factions, as sole teachers, and turn to the truly great achievements of the past. As form is undoubtedly the greatest and strongest element in art so is the sculpture of ancient Greece the finest art the world has ever seen, or may see. What has been lost to us in the destruction of the paintings of this period we shall never know, but we have the masterpieces of the Italian, Spanish and Dutch schools for our guides. The great elements of the work of these masters appeal alike to the painter and photographer; the same lessons in strenuous constructive lines, masses of light and shade, and harmony of colour.

Apart from these giants in art of the past, we have more modern painters, men of our own time and country, whose work is worthy of ranking with the highest. It is not the fashion just now to dilate upon the work of those three great painters of our English school, George Mason, Frederick Walker, and Sir John Millais, but their position is an undying one, and to them mainly the modern art of this country owes its glorious heritage of colour, which not long since made English art respected throughout the world. This legacy has been neglected of late years, and has suffered from the imitations of foreign methods, which have unfortunately tainted the inspirations of many men whose pride it should have been to uphold the reputation of what can almost be considered a trust left in their charge. Let us strive at all events to be original, not alone in a national sense, but as applied to the individual. No man yet obtained the respect of his fellows by founding himself upon another. It is so easy a thing, and so poor a thing, to be an echo.

### Figure Study May Inspire Creative Photography.

Modern photography has every reason to be warmly congratulated upon the great strides it has made, not only in matters pertaining to its scientific side, but also in the more important one of artistic quality. In the pictures of landscape we have a simple rendering of nature without any desire to dress it up, or prettify it, which is most healthful. The coming to the front of this appreciation of simple dignified subject matter is a striking feature in the advance of late years. Landscape photography of this order is the outcome of the most careful study, for the inexorable lines of nature cannot be moved, and any incongruity can only be circumvented by discriminating choice of the point of sight. Sometimes this has not been overcome, because, apparently, it could not be overcome, while retaining some important feature necessary to the picture. The difficulty of control of the subject is, doubtless, the stumbling block in the way of landscape photography; but when we remember that these very many fine things have been produced, under hampering restriction, the prospect of what might be possible in directions, where the artist had greater facilities, is of the utmost interest. The representations we have of studies of the sea are very impressive, particularly those which are not too sharp in their definition, and where the sense of movement has not been checked by a metallic crispness. In these we can estimate the beauty of the drawing seen in tumbling water, and the character and form of the masses of flying spray. Some of these breaking seas are splendid things. Many of the scenes showing the effect of evening are pleasing enough, though the prevailing tendency is to indulge somewhat too freely in indistinctness of focus, for some granular process is employed in the making of the prints, which invests the entire picture with the same quality. Nature always has a decisive note somewhere, of more or less emphasis. The work done in the direction of interiors is, with the facilities offered by the use of modern apparatus, most perfect as a record of the image before it. The figure subjects that one sees are fewer in number than the landscapes, but are perhaps the more attractive in one sense, for the photographer has greater responsibility here in his personal conception and arrangement of them, and his capacity as an artist is more directly brought before us. Many of these subjects are excellent, and some contain aims of a high order which would

seem to forecast the future of photography. For this is the direction to which the art ought to be strong enough to assert itself, where it can dominate its subject, and invest it with the creative.

### The Recording Camera.

In the commercial world photography is playing a strong part, and the publishers, and in the direction of illustrated journalism there is no doubt that it is doing a useful thing. I think that we must admit that the *bond fide* character of a photographic picture, which illustrates a topical subject, is one of far greater interest than the one of idealised treatment which we were familiar with in the past. We are bound to respect such pictures as fact, as true representation of the incidents depicted, which is exactly what is wanted for the purpose. We want in such cases to know what the incident was like, not what another man thought it was like. These matters, however, do not pertain to art, though there is one phase of such photographic work which has done an immense service to the world, and that is, it has enabled those who live thousands of miles away to have a complete image of people and countries they may never hope to see personally. Photography has practically brought to every country a true picture of all others. To science, as well as art, this is a great gift, not to mention the unspeakable interest to many thousands of families who are scattered widely apart. This is the great feat in the cap of photography.

### Education in Art.

One of the reasons of the greatness of art in the past is found in the fact that people lived in times when they were surrounded by the beautiful to a far greater extent than at the present day, and they became so familiar with it that a high standard of appreciation was reached, not only by the exponents of art, but by the public itself. In Greece the human figure was, of course, the dominant influence, in Italy the fine personality and grandeur of costume, in Holland and Spain the characteristic and the picturesque. Modern life cannot permit these surroundings, but the representations of such things hanging upon the wall, as painted by the great men of those times, produced an instructive influence which should be found in all establishments devoted to art. I am, unfortunately, rather ignorant of the methods of education which prevail among photographic societies, and my knowledge of photography of to-day is founded to a great extent upon the exhibitions of pictures that are seen annually on view in London. The scientific side of the subject evidently is well provided for, but one often wonders whether there is a course of training in art pursued in the societies, independently of the use of the camera itself. The student in painting is for some years occupied in schools of art, or the studios of painters, learning not only his craftsmanship, but educating his taste and forming his standard of beauty, in the study of the fine examples of art he finds placed before him. The importance of this can be hardly over-estimated. A man's cultured taste is not born with him. He, of course, may be born with a gift for art, but that gift is profitless unless it is educated and developed. Art is a most serious as well as a most beautiful study, and the student not only has to master the executive of his profession, whether with the palette or the camera, but he has to learn to compare, and mature his judgment to be able to select, for selection is the very principle of art. A landscape painter who has been drilled in the schools can apply the principles he has mastered there to the real work of his life—landscape painting—equally well with the man who intends to paint the figure. This would appear to be a vital element in the education of a student who is aspiring to produce works of art with the camera, for he, unlike the painter, has not the power of alteration or elimination when once the photographic plate is exposed. He therefore has to use the keenest judgment and taste in the preparation of his subject beforehand, which must necessarily be a most difficult thing to do, and will test his knowledge of art in a high degree. I am, of course, here alluding to the treatment of the figure subject, for with landscape the power of creation does not lend itself freely to photography, and beyond the choice of point of sight, and the waiting for the appearance of a satisfactory effect upon the scene, the scope afforded to the photographer for the exercise of the creative is limited by the intractability of his subject.

### Study the Living Model.

I do not know whether there exists such an institution as a photographic school for students to study from the living model, but such

school must undoubtedly prove of much value; and in the study of works of masters, by grouping human figures with an exact ability to resemblance, pose, lighting, and detail to the original nature, under the tuition of a photographer who was a master of the side of the matter, an opportunity of a most instructive nature would be found. If this idea should be new it may possibly not produce a favourable impression, for few innovations do. Personally, I believe that the greatest things that photography is going to do in the future will be associated with the figure; for, in connection with that, the photographer will have the best opportunity of developing and showing his creative power in art, and it is this very quality of the creative which is the charm. When we remember the exquisite modelling of flesh and the tenderness of tone which a good photograph can give, it seems a great loss that these qualities are not made available to the full extent. A student trained in art, working with fastidious care in selecting his model, and in conducting his whole operations, would, I am persuaded, if he was a man with imagination, produce some photographic pictures which would give a sensation. The actor's is an art—how much greater to make a figure so perfectly play a part that the resulting study should be received as a great picture. Beautiful as quantities of the landscapes which are seen in photographic exhibitions, they are the artistic comparative results which are possible in this direction, at the hands of the right man. If the day should come when a man, with the conception and insight of our painter, G. F. Watts, who combines that power with a photographic executive of the exactness of Mrs. Margaret Cameron's, the world will see for the first time what it is possible for photography to achieve.

### The Tragedy of Art.

But the pursuit of pure art is a thorny path to tread, and, if a poor man essays to venture his fate in this direction he must do so prepared to lead a life of stern self-denial and extreme patience. Even if he may have to contend not only with vicissitude, but with actual want; for recognition even of a truly distinguished man comes sometimes so late in life as to be valueless to him. A sadder case of this kind it is difficult to quote than the Frenchman, J. F. Millet, painter of "The Angelus." As there may be some present who are not acquainted with the struggle this eminent man had, perhaps a few facts from his life may be enlightening. The extracts are from the life of his friend Sensier, which is to be found in Vol. XX. of *Cribrer's Monthly*. Sensier relates how Millet, though leading a simple life of a peasant, could barely obtain the necessities of life for his family, and this was mainly done by his painting signboards for a few francs each, struggling to pay off his debts to the local tradesmen for their daily food. "Amidst these miseries," says Sensier, "his head always ill, and disquiet and fear always following him, Millet painted his most beautiful works—"The Gleaners," "The Angelus," and "Waiting."

"The Angelus" was painted in 1859, and sent to Paris, where it remained two months without an offer being made for it. This year he writes to Sensier:—

"It is frightful to be stripped naked before such people, not so much for one's pride, which of course suffers, as because it is impossible to get what we need. We have wood for only one or two days, and I do not know how to get it, as they will not give it to us without money. I am suffering and sad. Forgive me for telling you these things. I do not pretend to be more unfortunate than a lot of other people, but each feels his own pain. . . . I am working on the drawings of Alfred Feydeau, whose money I beg you to send as soon as you get it, for the children cannot be without a penny. Try, my dear Sensier, to coin some money with my pictures; I will them at any price, but send me one hundred francs, fifty, even thirty."

"Thirty francs!—twenty-five shillings! This was the year he painted "The Angelus." He died, as Sensier says, "killed before his time by the endless battles in which his strength could not but be exhausted." This is, I am afraid, very gloomy reading, but it is far from being the solitary instance of the world's greatest treasures being wrung from suffering humanity. It is an account which does apparently encourage a novice to try his fortune in the same direction. But to such a man as this work was more important than to him, and the world reaps the benefit, however much it may commiserate the sufferings of his family and himself.

### Instantaneous Photography.

I should like to make a few remarks upon one or two subjects, as a painter, though the subject-matter is more or less photographic. The first of these is what is called "Instantaneous Photography." Some time ago we had a visit paid to this country by a lecturer whose wonderful photographs of moving animals immediately arrested the attention of artists of all kinds. If the lecturer had contented himself with his own department, the photographic analysis of the movement of animals, all would have been well, but he demonstrated by single records of action, that is to say the action that is found in the 1-500th part of a second that the movement shown in the pictures of animals by Landseer, by Rosa Bonheur, and others, was incorrect. This is another example of mistaking a part for the whole. It is the object of art, in representing movement, to communicate to the senses of the spectator the sensation of movement as it appears to the human eye, and not as it appears to a photographic lens worked by a shutter at 1-500th part of a second. For instance, if a cart wheel, revolving quickly, is photographed by such a quick apparatus the resulting picture conveys the idea of a wheel at rest, for every spoke and detail is sharply defined. But contrast with this the conventional way of drawing a wheel revolving, a circle with a few irregular radiating lines proceeding from its centre, and you at once get the sentiment of motion. This is art. The other is mechanics. When the series of pictures was shown, one at a time, the quaint and extraordinary action of the horses provoked the audiences to amusement; yet when they were shown in quick rotation in the biograph and gave, in their combination, the suggestion of action which the human eye can appreciate, the applause of the spectators testified their pleasure. This is to be said of all representation of movement by Art—that they shall convey only to the eye what the eye is limited to seeing. Analytical demonstration beyond this steps out of the domain of art into that of science. It is the duty of art to represent the typical and not the exceptional. Please do not gather from this that I am not alive to the intense interest which subjects taken with the hand camera always possess. The photographs so taken must certainly appeal to every lover of Nature—if they have had enough exposure.

### Perspective in Portraits.

Another subject I should like to dwell upon is the photographic portrait, taken direct, on a fairly large scale. These portraits sometimes have a certain quality about them which prevents them being accepted as successful likenesses, although the expression is admitted to be natural, and the features individually faithful in identity. Now I would submit the opinion that this is the result of the camera being brought too close to the subject, and therefore exaggerating the perspective view of the face. While the human vision consists, as it does, of the combined images of the two eyes, the vision of the camera depends upon its single lens; and though a perfectly satisfactory image can be obtained, at a certain distance, by the two human eyes, because, from their different positions, they are able to look more or less round the sides of an object, the camera lens has but one point of sight, and, from the same distance, would yield a very different image, because it does not see round the sides of the object. This leads to undue prominence being given to the nose and front planes of the face. As an illustration of what is meant, let us suppose a view taken, of the front face of a human head as a model, so close to it that the ears would not be seen by the photographic lens, as they would lie behind the projecting cheeks of the face. The two human eyes, at the same distance from the face of the model, would see a portion of the ears, because from their two points of sight they would see round the cheeks of the model to some extent. The point of sight therefore for the photographic lens to be placed, to obtain the same view as that of human vision, is at the apex of the cone of rays which includes the visual angles of the two human eyes. The stereoscopic camera, with its twin lenses placed apart, as human eyes are, would obtain the same view of the model as the human vision—that is to say the combination of its two pictures would give the same view. This illustration is, of course, a much exaggerated one, but portraiture is such a subtle thing that the slightest variation in the proportion of the features is to be guarded against as a disturbing influence, and this difference between the human vision and what we may call that of the camera, should be remembered at all points of sight.

### Possible Virtues of Halation.

The other subject I will touch upon before concluding is that of diffused light seen in the interiors of buildings. Photographers have a wholesome dread of the quality which is called "halation," and, while it certainly is an eye-sore to see the tracery of a window obliterated by a flood of bright light, I really think it is quite as uncomfortable to have the detail of a window sharply picked out like the working drawing of an architect. The effect of diffused light about the interior of a cathedral is a most poetic element, and is one which some of our great interior painters have seized upon to construct their pictures with. Perhaps a medium course between the two extremes would be the safest one to adopt. At all events, if the photographer wants to make a picture, and not a portrait, of an interior, let him avail himself of this opportunity of obtaining such beautiful gradation of tone as the occasion offers.

It is this very quality of luminous haze that was so largely employed by Turner in the beautiful sunset scenes of his, in which he deliberately introduced the sun itself, and made magnificent use of the play of light upon the atmosphere, in managing the effect of his picture. It is well to speak of this great man Turner as an "Impressionist," for that he most certainly was, in the fullest sense, for he conveyed not only a most gorgeous impression of the effect of the scene represented, but also the detailed impression of the most infinite number of subtle gradations in the beautiful tones of distances, from the delicate film of the extreme horizon to the strong and full-blooded modelling of the foreground of his picture.

I have tried to discuss our subject by a high standard, which is the only one possible to take with the question of art, and it is the standard that all serious aspirants have to abide by in our profession.

It is a beautiful profession, and is, to a great extent, like virtue, its own reward. All that we, the members of it, can do, in its furtherance, is to strive to hold the mirror up to Nature; to tell the truth, the whole truth, and nothing but the truth. J. C. DOLLMAN.

The Chairman (Mr. David Murray) paid a high tribute to the excellent paper which had been read, and said he would take the opportunity, which he had never previously enjoyed, of expressing his views on the subject. He wished to ventilate his own delight in that most interesting pursuit, photography. When science sprang upon art, that wonderful invention, there was great alarm felt everywhere, and nowhere more than among portrait painters. There existed a letter from Sir William Beechey imploring the Lunar Society, one of the earliest of the photographic societies, to suppress their discovery, as otherwise the portrait-painter's profession would be ruined. Now quietly, gently, and absolutely, that alarm had subsided, and photography had proved to be a good friend to the portrait painter. But it had been a foe to him in some respects. The portrait painters had been in the habit of abandoning themselves fearlessly to portraiture as the expression of lines and quantities of grace, but they were compelled by the mirror which photography presented to them to give details which hampered them in much that was valuable and essential in art. He knew some portrait painters who had gone so far as to adopt photography as a basis of their work. Some had had a photograph of the sitter enlarged on to the canvas; they were almost compelled to do that because of the poverty of their powers of drawing. Some landscape painters had been addicted to the same habit. But he knew some portrait painters who were as infallible as the camera, almost, in their power to draw, yet who availed themselves of the photograph so that no fact should be omitted. He regretted that because it showed a tendency to cram the picture with details which were not essential factors. Of course, the camera was a great aid to the landscape painter, but he did not feel at home with it. If he could catch the ever changing clouds with it he would utilise that and discard the rest. Photography had been extraordinary serviceable in that it had enabled us to bring together reproductions from the finest collections of art throughout the world, and he had recently seen a huge volume of photographs of master-pieces in continental galleries, and had been amazed at the perfection of the photography when employed by a man who obviously must have been an artist. Every fact of interest worthy of the painter's atten-

tion was given, the quality of the canvas, the impress to the sweep of the brush, and the particular form of a chosen touch, as well as the time records on the surface. No man who had not the artistic instinct in a high degree could have taken such photographs. The only thing which seemed to be wanting was that precious thing—colour. Yet even colour seemed shortly likely to be embraced in the triumph of the man with the camera. He had found great delight in Camera publication, "The Nation's Pictures," which was issued at a cheap rate. He did not say the colours were perfect, but they, any rate, served to recall the actual pictures to those who had seen them. Some of the colour reproductions were extremely beautiful. With regard to the question of art in photography, Mr. Dollman had treated that part of the subject very well. The value of art training had been enlarged upon, and he agreed with it. He spoke highly of the valuable magazine, "The Studio," and he had been amazed at how near some of those reproductions were to the work of first-rate artists. Some of the pictures showed that a photographer might be a great artist. He spoke in terms of great admiration of Turner work, whom he described as that great giant on art, the biggest man in art in any realm of any time. The photographer as well as the artist might despair of ever being able to combine effects so beautiful as he had. He hoped there would always be impressionists, though the great bulk of them were not good, interesting, nor valuable. Many of them were impressionists because they could be nothing more; a half-finished or three-quarter-finished statement or conception in art was the most they could achieve, and they seemed proud of it. A perfunctory fashion of treating the most delicate treatment was not to be recommended, certainly not to the student. When master minds came to treat their work in an impressionist fashion was on the strength of well-based knowledge and a large facility of handling, and they were therefore entitled to it. Inspired by Turner's work, very many impressionists sought a path of their own, and the latest stage in Turner's art attracted them. It began by a number of French impressionists finding Turner's work so interesting that they resolved to work upon the methods which he had adopted, and to introduce the spectral tints all through their work. None had done that more intelligently, honestly, and perseveringly than Claude Monet. But when one gave all credit to his performances, one must admit with regret that Claude Monet had not painted pictures, he had painted wonderfully interesting exercises. Shall the day come when these exercises will result in great pictures? He would like to see that school abandon somewhat the practice of the prism tinting, and see the tinting controlled to one general aspect which would represent atmosphere as Turner represented it. Turner's work, with its wonderful compositions, its great artistic as well as scientific joy in colour, and its lovely surfaces of paint, delighted and convinced and remained with us for all time, ever growing greater as our own knowledge extended. The camera had its triumphs and its future, and he hoped it would ever extend its usefulness and progress. The chemical knowledge in connection with the camera seemed to be acquired by everyone with equal facility, and now there remained careful study of the art side of the question. He concluded by proposing a very hearty vote of thanks to the reader of the paper, which was carried unanimously.

Mr. Dollman, in reply, expressed his thanks for the vote which had been accorded him, and for the lenient way in which his paper had been treated in the discussion. With regard to combination printing in photography, it appeared to be a matter of great responsibility to do such a thing. He did not pretend to be an expert in photography, but he realised the fact that in Nature when one looks at a scene a certain scheme existed of light and shadow and tone, and interfere with which was in some measure to run the risk of marriage in its entirety. With regard to mechanical work on the negative, that would appear to produce a hybrid example of art for which at present there was no want, and it scarcely came under the subject for discussion. His aim in the paper was a conscientious effort to tell the truth from the points of view of the photographer and the painter, as the most serviceable way of bringing them together. He saw much in Nature than the impressionist did, and he could not recommend to anyone that which he did not believe in himself.

PHOTOGRAPHING NEAR FORTS.—A Londoner named Gardner, who was found taking photographs last week at Lido di Malamocco, in close proximity to the fortifications, was arrested on suspicion of

being engaged in espionage. His kodak was taken from him, and he was detained in custody for twenty-four hours, when his photographs were developed and found to be of a harmless nature.

# Photo-Mechanical Notes.

## Reproducing Medals.

PROCESS WORK" in its current issue publishes several replies to a query asking how to reproduce medals to secure the proper effect of relief. Several methods are given, viz., the master cast, spraying the medal with grey colour from airbrush, Hood's method of allowing smoke from burning magnesium ribbon to reach the surface of the medal, which is held face downwards over the burning ribbon, and, finally, the method of lighting with one lamp only. The last method may not be successful unless one other precaution is taken, and that is to keep the light moving to and fro and, if possible, up and down slightly, while the exposure is being made. If reflecting lamps are in use, this is perhaps the simplest and best method.

To fasten the medal on the board, it is advised that pins mounting brads should be used, but a better method has been shown to the writer by Mr. W. J. Smith, at the L.C.C. school. This consists in cutting an aperture out of millboard slightly corresponding to the shape of the medal, but slightly smaller. Cut this in half, lay the medal down on the copying board, and then place one half of the millboard on each side of it. These can be wedged up closely and then pinned down with drawing-pins, so that they hold the medal fast without any danger to it, and there is no fear of shadow from projecting parts nor anything to be engraved away afterwards.

## Contract Prices for Process Blocks.

The London County Council recently invited tenders for process blocks from several firms, and the matter is dealt with in the minutes of the meeting held on February 13, 1906 (to be obtained of P. S. King & Co., Westminster, price 6d.). Quotations are printed from five firms, the lowest being for line blocks 2d. per square inch, with minimum of 2s., all the other firms quoting 2½d. and 2s. 6d., for half-line blocks, minimum 4s. 9d., the rest quoting 5d., with minimum of 6s. The lowest quotation was accepted.

## Embossing.

Messrs. Bourne and Co. have issued an attractive little circular on embossing, in which they explain to the small printer exactly how to do it, and offer to help him in his work by making "proofs," and to sell him composition, with which he can do such work both well and cheaply.

## The Business Side of Photo-Engraving.

How is it that one business last year lost £1,000, while another, doing roughly the same turnover, made a profit of £2,000? That photo-engraving can evidently be made to pay with energetic and capable management appears from the prospectus of Carl Hentschel (1906), which shows that an average profit of over £10,000, or 8 per cent. of the capital, has been made for the past two years. The additional capital asked for by the company, it is reported, was fully subscribed before the time that the lists were to remain open had expired.

A series of four lecture demonstrations on duplicate plate-making, electrotyping and stereotyping commenced last week at the Art Court School, and will be continued on Thursday evenings. The first three are by Mr. J. S. Sunderland, and the last by Mr. Sherard Cowper Coles. Admission is free to students of the school; to others, 2s. for the course. Succeeding these lectures will be a course of seven lectures on three-colour and orthochromatic photography, commencing May 3. Further particulars will be announced in due course.

Platinum Deposits.—Telegrams from Shadrinsk, in the Government of Perm, the chief mining region of Russia, report the discovery of rich platinum deposits in the Ougry and Katchkomury districts.

# Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between March 5 and 10:—

SELF-TONING PAPERS.—No. 5,276. Improvements in the treatment of prints on self-toning paper. Francis John Shepherd and John J. Griffin and Sons, Ltd., 322, High Holborn, London, W.C.

CAMERAS.—No. 5,354. Improvement in photographic cameras. Clarence Claxton, Blagdon Turner, and Stanley Wyndham Jamieson, 321, High Holborn, London.

ISO SCREENS.—No. 5,603. Improvements in isochromatic screens. Thomas Baird, Stewart Baird, 96, Buchanan Street, Glasgow.

CINEMATOGRAPHS.—No. 5,626. Improvements in cinematographs and projecting apparatus. Arthur Samuel Newman, 23, Southampton Buildings, London.

PRINTING MASKS.—No. 5,670. Improvements in masks for photographic printing processes. Leipziger Buchbinderie Akt Gesellschaft vorm Gustav Fritzsche, 111, Hatton Garden, London.

REFLEX CAMERAS.—No. 5,673. Improvements in reflex cameras by the addition hereto of a swing back. Ernest Human, 43, Whitta Road, Manor Park, Essex.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

DARK SLIDES.—No. 19,032, 1905. The invention consists of a dark

slide with notches in the upper part of the case to obviate projecting shutters. Gustav Geiger, 16, Maximilian Platz, Munich.

ELECTRIC STUDIO LIGHTS.—No. 25,392, 1905. The claims is for a system of electric incandescent lights which allows (1) the distribution of the light to be regulated by placing the normally burning lamps without necessitating work with a too glaring light, and (2) the increase of the light by raising the potential merely during the taking of the photograph. Philipp Georg von der Lippe, 4, Bogittener Lande, Vienna, II.

The following Complete Specification is open to public inspection before acceptance under the Patents Act, 1901:—

STEREOSCOPIC PHOTOGRAPHS.—No. 5,267, 1906. Method and apparatus. Bug Ges m.b. H. zur Verwertung von Erfindungen und Barnack.

The second American Photographic Salon will be exhibited in New York by the Metropolitan Camera Club from May 28 to June 9. Officers of the club for 1906 are:—W. T. Knox, president; Dr. W. J. Furness, vice-president; S. C. Bullenkamp, secretary; J. Hunter, treasurer; E. Polasek, librarian; directors, Curtis Bell, B. F. Woodburn, L. A. Malkill, W. H. Zerbe, D. Elmes.

## Exhibitions.

### GREAT EASTERN RAILWAY MECHANICS' INSTITUTE.

THE Thirteenth Annual Exhibition was held on March 13 and 14, when the judges, Messrs. J. T. Ashby and H. W. Bennett made the following awards in the open sections:—

Prints.—Silver medal, No. 216, "In Old York," A. W. Walburn; bronze medal, No. 223, "Now Came Still Evening On," W. L. F. Wastell; certificate, No. 214, "In Blythburgh Church," L. C. F. Robson; certificate, No. 222, "The Edge of the Common," W. L. F. Wastell. Lantern slides.—Silver medal, set by A. Nicholson; bronze medal, set by Graystone Bird; certificate, set by H. Wormleighton. Stereoscopic slides.—Bronze medal, set by H. Wormleighton; certificate, set by A. Woolford.

### WALSALL AMATEUR PHOTOGRAPHIC SOCIETY.

THE Walsall Society held their bi-annual exhibition on Thursday, Friday, and Saturday last in the Assembly Rooms. It was opened by the town clerk, Mr. T. R. Cooper. A capital collection of members' work was shown in landscape, seascape, portraiture, architecture, flowers, novices' and lantern slides, in addition to a small but excellent loan collection. The list of awards, made by Messrs. Hughes, Harold Baker, and F. H. Pilditch is as follows:—

President's special prize awarded to Mr. Geo. W. Richmond for best in the exhibition (irrespective of class) for his picture entitled "This is the forest primeval . . ."

Landscape (Class 1).—1st (11), "Eckington Bridge," Mrs. W. Bullock; 2nd (4), "Among the Heather," W. A. Hubball; 3rd (25), "Walhouse Street," W. Meikle.

Seascape (Class 2).—1st (93), "Sunset," W. T. Comer; 2nd (87), "The Ebbing Tide," F. P. Farrington; 3rd (94), "On the Blyth," W. J. Brown.

Genre, Portraiture, etc. (Class 3).—1st (118), "The Bible," W. Meikle; 2nd (208), "The Parks' Keeper," W. James; 3rd (172), "Who Said Mouse?" Mrs. W. T. Comer.

Architecture (Class 4).—1st (142), "North Aisle, Gloucester Cathedral," Mrs. W. Bullock; 2nd (141), "Vale Crucis Abbey," W. A. Hubball; 3rd (144), "Crypt Ruins, Wingfield Manor," E. Holmes.

Flowers (Class 5).—1st (174), "Clematis, Labata Indiviser," G. T. Thompson; 2nd (168), "Basket of Flowers," Mrs. W. T. Comer.

Novices (Class 6).—1st (224), "Evening, Autumn," A. E. W. Aldridge; 2nd (222), "Dovedale," Alfred Ford; 3rd (197), "Washing Day," F. W. Hale.

Lantern Slides.—1st, J. H. Hubball; 2nd, J. Meikle; 3rd, J. H. Bullock.

They are energetic and businesslike in Walsall, and we are glad to hear that the exhibition has left a balance to be handed over to the Society's funds. The catalogue is quite an example to similar photographic societies in the way it sets forth (in photographs) the advantage of the Walsall Society, and it speaks well for the executive when we mention that it was on sale with the award list in it within two hours of the judging. Apparently the Secretary of the Walsall Society is a man feared of printers.

THE Coburn Exhibition at the Royal Photographic Society, Russell Square, remains open, we would remind our readers, only for a week or ten days longer. We hope that the opportunity of seeing Mr. Coburn's really great successes in portraiture has been or will be seized before it is gone. Admission to the R.P.S. is granted on signing the visitors' book, and we believe the exhibition is open daily (Saturdays included) from 11 to 5.

THE Bishop Auckland Photographic Society have decided to hold their third Triennial Exhibition on the 6th, 7th, and 8th November next. There will be open classes.

THE "Graphic" this week presents a new feature. In addition to the usual artistic illustrations, it contains the first of a series of supplements, entitled "Portrayed by the Camera," which is composed of four pages full of striking scenes from photographs taken at home and abroad.

## New Apparatus, &c.

"Pantar" Anastigmats. Made and sold by C. P. Goerz, 4 and 5, Holborn Circus, London, E.C.

These lenses are of the "convertible" variety, being composed of two anastigmatic "single" combinations, which may be of equal or different focal lengths according to the selection of the purchaser. Sets consisting of these combinations are also listed, and seven different single combinations, varying from 6 to 19 inches focal length, can be selected from. The particular lens submitted to us has two combinations of 11½ and 14 inches focal length respectively, and these form a doublet of 7½ inches focal length. This lens is specially recommended for a half-plate camera, and it will be noticed that the three focal powers available form a very useful series. In many lenses of this convertible type there is considerable difficulty in making allowance for the different values of the stops when the combinations are changed, but this trouble is non-existent with the Pantar. The front part of the mount is fitted with a loose ring, on which are engraved the three aperture scales for the three different focal lengths. By turning the ring the proper scale is brought opposite the datum mark on the iris ring, and is locked in that position by a simple catch, so that there is no fear of its shifting. Another common trouble with convertible lenses is the amount of screwing and unscrewing necessary when changing the combinations. This trouble is disposed of in the Pantar by fitting the combinations and all the flange with interrupted screws, somewhat similar to those employed in breachloading guns. It is only necessary to place the two parts in contact opposite certain datum marks, and then a quarter turn to the right makes all fast. The arrangement works perfectly and is of the greatest possible convenience. Those who have occasion to use these lenses will probably soon regret the fact that all lenses are not similarly fitted. Another very material improvement in the mount is the provision of a fixed milled ring, by means of which the lens can be turned when fixing it in the flange. As a rule the iris ring is the only convenient portion of the mount to grasp, though it is eminently undesirable to put such a strain upon the delicate iris mechanism. The full aperture of the doublet lens is  $f/6.8$ , while that of each single combination is  $f/12.5$ . (Some of the "Pantar" lenses, however, work at  $f/6.3$ ). According to the statements in the list, the doublet covers a whole plate at full aperture, while the 11½ inch combination covers 9 x 7, and the 14 inch covers 10 x 8. From our tests it would appear that these claims are somewhat under the mark. In all cases the lens appears to cover a little more than the size mentioned. The doublet stopped down to  $f/32$  covers a 10 x 8 easily, and with a little more stopping down will very nearly, if not quite, cover a 12 x 10. The 11½ inch combination is said to cover 10 x 8 with  $f/22$ , and 12 x 10 with  $f/16$ , but it appears to cover both sizes very fairly well at larger apertures. The 14 inch, naturally, will cover a somewhat larger plate. It covers 12 x 10 easily at  $f/22$ , and is stated to cover 15 x 12 at  $f/16$ , but the latter statement we could not check, as 12 x 10 was the biggest camera available. If the use of the Pantar lens is confined to the plate for which it is recommended its performance seems to be faultless, and its great covering power permits the rising front to be used to the greatest advantage. With the 14 inch lens in front of the 11½ inch, the field appears to be quite flat for objects at a moderate distance, but with the lenses reversed a barely perceptible curvature is introduced. In regard to this matter of flatness of field, even the single combinations (each consisting of four lenses) seem to be as efficient as the doublet. It is, of course, difficult to test marginal corrections very exactly when the lens is used at a very wide angle and stopped down, but so far as we could observe, no fault could be found with the performance of the 7½ inch doublet on a 10 x 8 plate at  $f/32$ . The doublet, being non-symmetrical, was not expected to give an exactly perfect result when used for copying at full aperture, but we tried it for copying a diagram on a reduced scale of 4 to 7, and found only very slight curvature of the field, and no sign of astigmatism. A test on the tourniquet showed that the nodes of the doublet are separated by about one-fifth of an inch, and the front one nearly coincides with the centre of the iris ring. The second node of the 11½ in. lens is about 2 in. behind the iris ring.

and that of the 14 inch lens about 2.4 inches behind. The fixity of the nodes when the lens is rotated indicates that the lens is practically free from distortion, and no sign of this defect was observed in the image. For copying purposes the non-symmetrical Pantar may not be quite up to the celebrated Series III., or "Daguer," as it is now called, but for more general work the new lens seems to perform as finely as the older one, while its convertibility and the fine correction of its single components are very material advantages. The particular lens submitted to us is as perfect and as convenient an instrument as can be desired for half-plate work, while it forms an eminently useful lens for much larger sizes.

Goerz Telephoto Attachment. Made and sold by C. P. Goerz, 4 and 5, Holborn Circus, London, E.C.

This consists of a tube with tele-negative lens and rack focussing adjustment with scale of magnification. The negative lens appears to be a combination of a very deep plano-concave cemented to a positive meniscus. The complete lens submitted had a 3-inch negative lens and a "Celor" No. 1 front positive of six inches focal length and aperture  $f/4.8$ . It is claimed that this telephoto attachment gives greater covering power than is usual with similar combinations. This is somewhat difficult to test in the absence of other telephoto lenses suitable for comparison, but the new lens certainly covers quite up to the limits given in the list, and apparently beyond them.

With a magnification of 7 it is claimed that it will cover a whole plate sharply, while it will also cover  $11\frac{1}{2} \times 9\frac{1}{2}$ . We find both claims fully borne out, and, in addition, that the whole plate is covered with full illumination at the largest aperture. The lens is compact, and with positive attached the total projection from the flange is only four inches. It is well known that distortion is a defect that cannot well be eliminated in any telephoto lens, and though the distortion is not usually apparent if the lens is kept at right angles to the plate, it is often easily detected if the lens is tilted while the plate is vertical. Applying this test to this lens we found indications of distortion of the "barrel" variety. Other well-known telecompounds frequently give "cushion" distortion under similar conditions. There is a small matter in connection with the flange screw to which we may call attention, as it should not be difficult to avoid it. With the complete telephoto combination both the aperture scale and the magnification scale can be brought into convenient positions for reading by properly adjusting the flange on the camera front. But if the teletube is removed and the positive lens used alone, the aperture scale then comes in a most inconvenient position under the lens. A little readjustment should put this right, and the defect is worth noting, as it is not altogether an uncommon one in such combinations. One other point is that the magnification scale is on the opposite side of the lens to the focussing screw. We found this somewhat inconvenient when using a high tripod and long extension, and it would certainly be better if the scale were placed nearer the screw, so that it could be read at the side from which he screw is operated. We hope that the makers will soon see their way to adopt the interrupted flange screw as used in the "Pantar," for it is by no means easy to induce these heavy objectives to enter a flange that is fixed to the camera front.

## New Materials.

Pluto Matt Collodion Paper. Sold by the Leto Photo-Materials Company, Ltd., Rangoon Street, London, E.C.

An addition to the numerous printing-out papers, gelatine and collodion, on the market, must possess some distinct quality to justify its appearance. In the case of the new "Pluto" paper, a supply of which we have had under trial for some time past, the novel qualities are not such as merit the term "revolutionary," but they imply certain simplifications in the photographer's practice which, we venture to think, will be appreciated in professional establishments. "Pluto" is a collodion paper toning to a rich black in a single platinum bath. The results are of peculiar richness and depth from negatives with a good deal of shadow, whilst on the other hand the pure black of the image is seen to very great advantage in subjects such as vignettéd portraits of ladies in light

costumes consisting almost entirely of the lighter tones. We subjected the paper to a series of trials from negatives of both such classes, and we found the range of gradation stood us in good stead in the case of the first-named class of negative, and, as we have said, the rendering of lace and drapery especially pleased us. "Pluto" being a collodion paper needs the particular precautions which that vehicle of the silver salt demands, but if the very concise instructions for the use of the paper be followed we cannot imagine a much simpler manipulation. The chief point to be noted is to use all solutions lukewarm, 65 deg. to 70 deg., and all as near as can be equal in temperature. After a preliminary wash for 5 mins. place the prints in a platinum bath of: Water 30 oz., citric acid 2 drams, potass. chloroplatinite 5 grains. In this bath the prints tone visibly, and the action, we find, should be allowed to proceed to its limit—in fact, it is difficult to over-tone—i.e., until a uniform grey is observable on looking through the print. A subsequent wash for fifteen minutes and fixation for another fifteen in 1-15 hypo completes the process, save for the final washing of about one hour. With the precaution as to temperature taken, there is very little sign of curling, but in cold solutions there will be quite an inconvenient amount of curl. However, there is no need to disregard the makers' instructions, and, if they are followed, the paper, it is our experience, will be found to give extremely rich and beautiful results by a procedure which leaves very little loophole for waste.

Simplex Self-toning P.O.P. Made by the Paget Prize-Plate Company, Watford.

The Paget collodion self-toning paper having been a standard make of such materials, and the first, we believe, to appear on the market it was to be expected that its makers would at length produce a gelatine paper for the use of those who pin their faith to the latter description of printing medium. The "Simplex" paper is the result. The method of using it consists in (1) fixation (with toning) in hypo, and (2) washing for about one hour. In regard to the hypo bath, the company find a strong bath conducive to the colder purple tones, and a weaker one sufficient for the warmer sepias. They therefore recommend strengths as follows:—

Hypo, 4oz. to 8oz. per pint for 6 or 7 minutes (cold and warm purples).

Hypo, 2oz. to 3oz. per pint for 10 minutes (sepias).

Hypo,  $\frac{1}{2}$ oz. to  $1\frac{1}{2}$ oz. per pint for 15 minutes (browns and reds).

Acting upon this recommendation, we find that the paper gave us a fine range of results particularly of warm brown and purples. The matt "Simplex" prints also fixed in 1:20 hypo for fifteen minutes have a fine warm brown tone very suitable for striking portraiture. The paper is put up in 6d. packets in sizes up to 6 by 4 $\frac{1}{2}$ , and in 1s. packets from half-plate to 10 by 8.

The "Amauto" (Self-Developing) Plate Made by Ilford, Limited, Ilford, London, E.

In the "Amauto" plate, the Ilford Company offer a new manufacture of theirs, which, it is safe to say, will be received with unfeigned interest throughout amateur—and therefore throughout dealer—circles. A plate, with developer included, is not a new proposition on paper, and it has even appeared on the market. Yet it has never been marketed in a large way through such channels as the Ilford Company hold at their disposal, and therefore the experiment of offering the amateur photographer his plate and developer all in one will be watched with interest. The new plate is exposed like any other, and is developed in a 10 per cent. solution of washing soda (carbonate of soda). Reasonable alterations in the strength of this solution, so we find, have no effect on the development, and therefore it is safe to advise a fairly rough and ready method of making up the soda such as those who shun all kinds of weighing and measuring will not consider troublesome. Treated in the developer which is thus formed by the solution of the developing constituents in the plate, the "Amauto," in our experience, behaves like any other plate, and is amenable to the well-known methods of protracted development—in a full strength solution for over-exposure, and in a weak solution for under-exposure. The negatives resulting from some fairly correct exposures were beautifully clean, and obviously the incorporation of the developer had not in any way disposed the emulsion to fog. The manufacture of such a plate is no small technical achievement, and we may congratulate the Ilford Company on adding

yet another to the manufactures by which, throughout its history, it has sought to popularise photography.

In accordance with our custom, we give the sensitometric data obtained by the method of Mr. C. E. K. Mees, B.Sc., which, we believe, are appreciated and used by some scientific workers:—

Inertia .320,  $\gamma_{\infty}$  (i.e., density giving power of the plate) 1.83. The peculiar character of the plate precludes the determination of other data which we are accustomed to give, but the above figures show that the plate is a rapid one—of speed ample for hand-camera work under conditions which may fall considerably short of the most favourable.

A SEPIA toner has been added to the numerous excellent "tabloid" chemicals of Messrs. Burroughs Wellcome, who, in bringing it to our notice, express pardonable pride in the production in "tabloid" form of such an extremely deliquescent body as pure sodium sulphide. The bleaching solution is made by dissolving one "tabloid" of ferricyanide and bromide in 4 oz. of water, and we find it act effectively and quickly, though whether its action is due, as Messrs. Burroughs Wellcome suggest, to the admixture of the two constituents in proportions based on their combining weights, we must decline to say in the absence of knowledge of the exact action of the mixture on the silver image. The purity of the products, however, is obvious from the rich tones obtained, and we can recommend the new cartons of "tabloids" for the convenient toning of bromide and gaslight prints. The "tabloids" of "bleaching compounds" (ferricyanide-bromide) and sodium sulphide are sold separately.

"Tyo," the sulphide sepia toner, which we believe was the first of these preparations to appear on the market has recently been reduced in price by its makers, Messrs. Wells and Co., Southgate. The present sixpenny size is about equal to that previously sold at 1s. Messrs. Wells issue a circular, explaining the use of "Tyo" for reducing, stain removing, and intensifying, in addition to toning.

A sepia-toning set has been placed on the market by Messrs. John J. Griffin and Sons, Ltd. It consists apparently of the two solutions of ferricyanide-bromide, and sodium sulphide, and has proved itself capable in our hands, of excellent sepia-toned prints. One quite novel feature, however, of the set is the provision of a bottle of potassium permanganate solution, which is included, with the object of removing from the process its chief reproach, that of smelliness. As Messrs. Griffin point out, the strong solution of the sulphide or "toning" bath, can be kept without offence. It is in its diluted state, and when poured away down the sink that it leaves the objectionable sulphur odour hanging in the air. The remedy Messrs. Griffin find in the destruction of the sulphide. The "toning" bath is not thrown away until after the addition to it of enough permanganate solution to give it a strong pink colour. It is thus rendered odourless and can be discarded without leaving a sulphuretted souvenir of its presence about the dark room. The chemical device we find works satisfactorily in practise, and Messrs. Griffin certainly deserve the thanks of photographers for their very practical suggestion. In each set of the new toners enough permanganate is provided to destroy all the sulphide.

PANCHROMATIC flashlight candles and powder, made by Dr. Krebs and supplied by Messrs. A. E. Staley and Co., 19, Thavies Inn, London, E.C., are the subject of a circular of instructions which presumably can be obtained from the latter firm, and in which are described the method of using the candles for orthochromatic work such as portraiture, copying without a screen. The flash candles are easy to use, and should be found of service in many cases where orthochromatic copies of paintings or works of art have to be made.

A sample of "Celeritas" retouching medium is sent to us by Mr. J. Taylor-Williams, 40, Wymering Road, Elgin Avenue, Maida Vale, by whom we are informed that, after continual improvements, it is offered by him as a practically perfect medium. It is sold at 6d. per ounce bottle, post free.

MESSRS. MAWSON AND SWAN are moving with the times in popularising the use of orthochromatic plates. Their enterprise takes the form of a free offer to users of the Mawson "Ortho. A" or "Ortho. B" plates. Commencing from April next a label will

be issued with each packet of these plates during the season, which label, if forwarded to the makers, will bring to the user a light-filter, enabling him to test the improvement in colour-rendering obtained by the use of an approximately adjusted yellow screen. The light-filter is supplied as a stained film, 2in. square, and can be mounted in the lens diaphragm or in a card mount placed before or behind the lens. It is not offered for permanent use, but for a user's first personal experiments in orthochromatism. For regular work Messrs. Mawson and Swan have their "ten times" and "twenty times" filters, the former for the "B" and the latter for the "A" plates, and, in regard to these permanent accessories, they also make a free offer: To the first fifty applicants who purchase not less than 10s. worth of ortho plates as issued from April, 1906, they will send one of Mawson's "amateur" light filters free on receipt of the top label from the packets showing the batch number of the plates purchased.

## CATALOGUES AND TRADE NOTICES.

A new catalogue of lens and other apparatus has been issued by Messrs. Voigtlander, and is obtainable, upon receipt of 6d., from 12, Charterhouse Street, Holborn Circus, E.C., or is sent free to the trade. The list is a good deal more than a comprehensive list, as it contains a lengthy series of notes on the selection and use of lenses by Dr. H. Harting, F.R.P.S., a study of which we would recommend to many of our querists on optical matters. In addition to specifying, in full, the various "collinear" and "Helier" lenses, the list describes the Voigtlander studio, folium, and reflex cameras, focal-plane, and other shutters, light filters, and reversing prisms. It is illustrated with a large number of half-tones, and is, in short, a handsome volume worth possessing.

In the current "Elge" list of cinematograph films, Messrs Gaumont commence a series of Bible subjects.

The British Photo Mount Company, of A2, Meart Street, Dean Street, London, W., advise us that they have taken over the business of the late firm of Messrs. Ernest Wesson and Company, of 122, Regent Street.

SOME specimens of adhesive seals for mounts are sent to us by Mr. F. C. Clarkson, Head Street, Colchester. They certainly add to the appearance of a finished and mounted photograph, and are obtainable at a small expense in a variety of styles and colours.

"POPULAR Photography."—Messrs. Butcher and Sons, of Camera House, Farringdon Avenue, E.C., have issued a booklet under this title. It is an elementary introduction to amateur photography and for free distribution by dealers.

THE new season's photographic list of Messrs. James Woolley, Sons, and Co., Manchester, which reaches our table, is specially worthy of commendation for the way in which a very large variety of goods are catalogued in small space. The list is a very full one, but, from its compressed arrangement, of moderate size, and easy of consultation.

A VERY full list of photographic mounts is sent to us by the Leipziger Buchbinderei Actien Gesellschaft vorm Gustav Fritzsche of Leipzig, Germany, who enclose with it a few examples of their manufacture. The latter are of the pastedown and slip-in variety, including, also, some of the latter class, with a supporting strut. The list describes these and a very large number of mounts by aid of half-tone illustration in every case, and should, therefore, be found convenient by British dealers, though, we fear, the company cannot expect buyers here to order from a list in German. The prices are per 100 and 1,000, and for the convenience of their customers the firm puts up specimen packets specially suitable for dealers purchasing in gross, and for these latter to show to their amateur customers.

THE sudden death is reported of Matthew Boak, aged 70 years, retired photographer, formerly of Driffild, at Lyell Street, Scarborough, last week.

EXCURSIONS to Zealand and Belgium.—The programme of the Easter trips arranged by Mr. W. F. Slater, under the auspices of the South London Photographic Society, is now ready, and can be obtained from 84, Longhurst Road, Lee, S.E.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
23.....	Aberdeen Amat. Photo. Assn.	Enlarging. Demonstration.
23.....	Aberdeen Photo Art Club .....	"Retouching." Mr. W. Dunn.
23.....	Colne Camera Club .....	Yorkshire Photographic Union Invitation Print Fello.
23.....	Hampstead Scientific Society .....	"Colour Photography." Mrs. Edward Shenton.
23.....	Bromley Camera Club .....	Evening for Discussion.
23.....	Loughton Photographic Society .....	"Rambles Round Loughton." Mr. W. Vincent.
23.....	Sutton Photographic Club .....	Platotype Printing.
26.....	Scarborough and Dis. Ph. Soc.	Members' "Lantern Lectures."
26.....	Dewsbury Photo. Society .....	Exhibition of Members' Prints.
26.....	Southampton Camera Club .....	"Eastern Valais. Visp to Zermatt." Illustrated. Mr. W. R. Kay.
26.....	Derby Photographic Society .....	"Enlarging on Bromide Paper by Daylight." Mr. C. B. Etches.
26.....	Cripplegate Photo. Society .....	"Pictorial Photography from a Practical Standpoint." Mr. A. Borsley Hinton.
26.....	Oxford Camera Club .....	"Side-lights on Portraiture." Miss Hopkins.
27.....	Royal Photographic Soc. ....	Technical Meeting. "The Application of Spectro-Photography to Technical Chemistry." Mr. T. Thorne Baker, F.C.S.
27.....	Otley & Dis. Cam. & Ars Soc.	Members' Print and Lantern Slide Exhibition.
27.....	Gateshead Camera Club .....	"The Toning of Bromide Prints and Lantern Slides, and Intensification and Reduction of Negatives by Tabloid Brand Chemicals." Messrs. Burroughs, Wellcome & Co.
27.....	Manchester Amat. Photo. Soc.	"Portraiture." Mr. Harold Baker.
27.....	Nelson Photo. Society .....	Lecture. Dr. Biru, M.B., C.M.
27.....	Darlington Camera Club .....	"Velox and its New Application." Demonstrated. Messrs. J. J. Griffin & Son.
27.....	Halifax Camera Club .....	"Evening Work with a Daylight Enlarging Camera." Mr. W. Wadsworth.
27.....	Worthing Camera Club .....	"Stories without Words." Prize Slides lent by Focus.
27.....	Birmingham Photo. Society .....	Lantern Evening.
27.....	St. Helens Camera Club .....	"Bromide Papers." Mr. H. R. Lacey.
27.....	Brentford Photo. Society .....	Discussion of Summer Programme, &c. Members' Evening.
27.....	Gloucestershire Photo. Society .....	Yorkshire Photographic Union Lantern Slides and Photography Competition Prize Lantern Slides.
27.....	Sheffield Photographic Society .....	Members' Slides (Lectures).
27.....	Jersey Photographic Society .....	Platotype Printing.
27.....	Cardiff Windsor Amat. Ph. Soc.	"Exposure and Exposure Meters."
27.....	L.C.C. Staff Camera Club .....	"English Ecclesiastical Architecture, from the Conquest to the Reformation." Mr. Chas. B. Howdill.
27.....	Leeds Photographic Society .....	Demonstration. Mr. F. W. Massey.
27.....	Burton-on-Trent Nat. His. Soc.	"Enlarged Negatives." Mr. F. Carter.
27.....	Cricklewood Photo. Society .....	Lantern Slide Demonstration. The Walthamstow Photographic Society.
28.....	G.E.R. Mechanics' Institution...	"Under Canvas: A Chat on Camping." Illustrated. Mr. J. Marston.
28.....	Leeds Camera Club .....	"Gum-Bichromate Printing." Mr. J. C. S. Mummery.
28.....	North Middlesex Photo. Soc. ....	"Our Portfolio."
28.....	Coventry Photo. Club .....	"Zig" and the Carbon Process." Thos. Illingworth & Co. Ltd.
28.....	South Essex Camera Club .....	Cameras and Lenses Described and Discussed." Mr. E. F. Smith.
28.....	Acton Photographic Society .....	A Popular Evening. The Y.P.U. Set of Loan Lantern Slides, Comprising the Selected Work of the Federated Societies. About 130 Slides.
28.....	Huddersfield Nat. and Ph. Soc.	Lecture Competition.
28.....	Croydon Camera Club .....	Annual General Meeting and Election of Officers.
28.....	Tring Camera Club .....	"Development." Demonstrated. Mr. J. Hawkins.
28.....	Everton Camera Club .....	Prize Slides. "Stories Without Words."
29.....	Hastings and St. Leonards P.S.	"Morocco: its Court, People and Customs." Illustrated by Lantern Slides and Motion Pictures. Mr. C. Rider Noble.
29.....	Blenheim Club .....	"The Pilgrim's Way from Winchester to Canterbury." Dr. J. W. Ellis, F.R.S.
29.....	Liverpool Amateur Ph. Assn. ....	Photography 1905 Prize Slides.
29.....	Richmond Camera Club .....	"Carbon Process." Demonstrated.
29.....	Tunbridge Wells Ama. Ph. Assn.	Thos. Illingworth & Co.
29.....	Darwen Photographic Assn. ....	"Through Nature's Eye-paths with a Camera." Mr. J. W. Smith.
29.....	London and Prov. Photo. Assn.	"Photographic Sketching." Mr. W. R. Stretton.

ROYAL PHOTOGRAPHIC SOCIETY.—A lantern meeting was held on Tuesday, March 20, when Mr. J. F. East lectured on the Victoria Falls. Major-General Waterhouse occupied the chair.

SOUTHAMPTON CAMERA CLUB.—At the meeting on Monday evening last, Mr. W. W. Clayton gave an illustrated lecture on "New Zealand." The chief cities of the colony, their industries and buildings, and the wonderful natural beauties of the islands, were all dealt with, while much interest was imported by way of the occupations of the Colonists and of the Maories being vividly depicted.

CROYDON CAMERA CLUB.—A discussion took place on hand cameras on the 14th inst., a large number of members taking part in it. During the evening the president, Mr. W. H. Smith, showed, and explained the action of, various types. These included Marion's focal-plane Reflex, a first-class instrument, obtainable at a moderate price; Beck's extremely ingenious Dai-Cornex, with daylight loading sheaths; the well-known "Sanderson," by Houghtons, Ltd., together with two pocket cameras, one for roll-film, and one for plates, by the same makers; and last, but not least, the Houghtons' recently introduced film envelope and adapter.

CHELSEA PHOTOGRAPHIC SOCIETY.—Lecturing on "Rotograph" bromide papers, on March 13, Mr. Jackson recommended the hypso-alum method of toning for ease of manipulation and permanence of results. He dwelt on the necessity of ripening the bath by letting it stand some time or by heating it with waste strips of silver or bromide paper in it. An unripened bath had a tendency to bleach the prints.

THE PHOTOGRAPHIC CLUB.—At the meeting held on Wednesday, March 14th, Mr. A. W. Green, for Messrs. J. J. Griffin and Sons, showed the firm's new automatic enlarger, the "Autokon," and explained its action. All agreed that it was a very ingenious instrument. The Hon. Secretary then demonstrated the "Pigment Paper" of Mr. J. Page Croft. He explained that the paper could be purchased in the sensitive or insensitive condition. In the former condition it would keep good for about a month under pressure, and the latter indefinitely. The sensitising bath was:—Stock solution—Potass bichromate, 1oz., pure sulphuric acid, 1 drachm; water 10oz. One ounce of this was added to 7oz. of water for use. The paper was immersed in this at as low a temperature as possible for 1½ minutes, then drained and dried. It was about four times as sensitive as P.O.P., but the exposure should preferably err on the side of over rather than under. The paper was then soaked in cold water and removed to the developing bath. The bath recommended by Mr. Page Croft was of warm water, to which was added a small portion of caustic soda. The demonstrator said he has used ordinary washing soda instead, and preferred it as development was more under control. About ten times the quantity of crystals were added as of the caustic recommended in instructions. Some exposed prints were then developed, and the amount of control over the results was shown. As soon as prints started developing in the soda bath they should be transferred to cold water and treated in that with transference back to soda bath as required. For ordinary correct exposure, bath should be comfortably warm, but for over-exposure temperature could be increased proportionately. A large number of prints sent down by Mr. Page Croft were then passed round and admired. They showed the tremendous amount of control over results possible. One set of prints from the same negative, showing the four seasons, moonlight, night, etc.; effects produced by suitable exposure and development.

FAILURE of a Photographic Journalist.—Percy Eland Newstead, journalist and theatrical manager, residing at Grange Cottage, Idle, appeared for his public examination at the Bradford County Court on March 14, before Mr. Registrar Lee. The statement of affairs filed by the debtor disclosed a deficiency of £583. In reply to questions put by the Official Receiver, debtor stated that prior to 1901 he was a journalist and black and white artist, and a sub-editor of the "Practical Photographer." He had offices in Piccadilly, and afterwards in Market Street. He produced several pantomimes at St. George's Hall, and afterwards joined in the production of a weekly journal called the "Jackdaw." They lost about £7 a week from the first issue, and when the journal ceased to exist in April, 1905, the total losses were £400. His theatrical productions visited Salford, Halifax, Middlesbrough, and Scarborough. The cause of his failure was his inability to find money with which to pay salaries. Upon the application of Mr. J. Richardson the examination was closed.

## News and Notes.

MESSRS. Rae, Limited, of Glasgow, notify us that they have secured premises in Dumfries, and will open early in April a branch of their business. Full stock of everything optical, photographic, and electrical, is to be kept, and they will arrange a dark room for customers' use.

PHOTOGRAPHY in Siam.—We learn that a very interesting feature of the Dusit Park Fair this year will be the exhibition of amateur photographs. The judging committee is: H.R.H. Prince Chao Fa Nakon Sawan, H.R.H. Prince Damrong, H.R.H. Prince Mahisa, H.R.H. Prince Rajburi, Mom Rajawongse Suwapan, Mr. Schuyler, Judge Skinner Turner, and M. de la Mahotiere. Each visitor to the exhibition may vote also for any photograph which he thinks deserves a prize by purchasing a ballot. No restriction will be placed upon the number of ballots, which can be bought by any one person. The number of votes will be counted each night. At the conclusion of the fair, prizes will be given for the photographs receiving the highest number of votes. There will also be a lottery on the following system:—Tickets will be sold at four ticals. Each ticket will bear the number of a photograph on exhibition, and the winning numbers will be the numbers on the photographs to which the committee award gold medals.

PHOTOGRAPHIC Society of Ireland.—Entries for the forthcoming exhibition, we may remind our readers, should be in the secretary's hands at latest on Monday next, March 26. They should be addressed to 194, Clonliffe Road, Drumcondra, Dublin.

THE annual meeting of the Yorkshire Photographic Union will be held on Saturday, April 7, in the Town Hall, Bailey. In addition to the business meeting there will be an exhibition of members' work, and a conversazione.

PHOTOGRAPHS to Measure.—We read in an Irish paper that a photographer in a country town was recently visited by a young woman, who, with sweet simplicity, asked: "How long does it take to get your photograph after you have left your measure?"

THE Northumberland and Durham Federation.—At the annual meeting last week, amateur photographers endorsed with applause two proposals of a fairly ambitious character made by the President (Mr. Walter S. Corder, North Shields). Mr. Corder put the question: How could they best help to increase the success of photography in the Northern counties? He suggested that the honorary secretaries of the local photographic societies should induce their members to join forces with the Society of Antiquaries in carrying out a careful and systematic survey of Northumberland and Durham, whereby there might be secured a permanent record of the vanishing objects of historic and antiquarian interest in the two counties. Further, he warmly commended the idea of utilising the Newcastle Art Gallery for an exhibition which would satisfactorily represent the possibilities of photography, with examples of the productions of the best amateur artists in the world.

A FIRE broke out last week in the photographic studio occupied by Mr. John Phillips, at 45, Donegall Place, Dublin, but the brigade extinguished it before any serious damage had been done.

DEATH of Hermann Schnauss.—We regret to learn from "Photographische Chronik" of the sudden death from an accident of Herr Hermann Schnauss, editor of our Dresden contemporary, "Apollo." Herr Schnauss was an old photographic journalist in Germany, and was known to readers of the British Press by his occasional contributions on photographic progress, and by the translations of photographic text-books from his own or others' pens.

THE Photo-Secession.—We learn from Mr. Alfred Stieglitz that the series of house exhibitions held in the small galleries of the Photo-Secession, 291, Fifth Avenue, New York, have been visited in large numbers by art lovers and members of the cultured classes generally interested in the aspects of art photography. During the fourteen weeks the exhibitions have been held between 8,000 and 10,000 persons have visited the gallery, and Mr. Stieglitz, who has taken upon his shoulders the promotion and arrangement of the exhibitions, and has himself superintended the minutest details of the hanging, may be congratulated on having won many new friends for the photography of the highest kind. The exhibitions have been

of fortnightly duration, and have included the work of Mrs. Käsebier and Clarence H. White, of J. Craig Annan, Fredk. H. Evans, and the late D. O. Hill, and of Eduard J. Steichen, including examples of his experiments in colour photography. On Monday next a "Salon des Refusés" is to be held for a fortnight, in the shape of a collection of paintings by American painters which have been refused at the Society of American Artists, National Academy, Carnegie Institute, and Pennsylvania Academy of Fine Arts Exhibition. Then follows a collection of multiple gum prints by German and Austrian photographers—Hugo Henneberg, Heinrich Kühn, T. and O. Hofmeister, and the late Hans Watzek, and the season will close with a general exhibition of work by members of the "Photo-Secession." Mr. Stieglitz's untiring labour in the holding of these exhibitions and in the production of "Camera Work," we see, conquers the opposition which he has had to fight in some of the American photographic journals, and our only regret is that the absorbing duties of administration leave him such scanty leisure to devote to his own photography.

THE Paget Prize Plate Company, Ltd., inform us that Mr. C. Lafosse has joined their staff as demonstrator of their various plates and papers.

It is reported from Vienna that the company formed to work Szczepanik's photographic process of producing patterns for weaving and textile materials in three colours has gone into liquidation. The reasons for the non-success of the company are stated to be that the patterns cost more to make by his method than by the usual hand work, and, further, the large patterns were found to be so fuzzy at the edges as to be quite useless, and thus after six years' experimenting the company wound up. Szczepanik himself ascribes the failure to the fact that he was called up for military service, and therefore could not superintend the manufacture of the machines, etc.

NORTH MIDDLESEX PHOTOGRAPHIC DINNER.—The annual dinner was held at the Holborn Restaurant on Saturday last, Mr. H. Stuart, the newly elected president, in the chair. The menu card and programme, which is an invariable feature of this annual function of the Society, contained reproductions of photographs to which awards were made at the 1905 Exhibition. Mr. E. T. Holding, who, with Mr. B. Gay Wilkinson, acted as judge of the Exhibition, presented the certificates and added some caustic comments on Mr. G. Bernard Shaw's comparisons of the work of Coburn and that of the old masters. Pursuing a vein of satire, he suggested that the successful exhibitors should divide up the old masters between them and show how their work could be challenged by photography. He thought Mr. Child Bayley might tackle Turner, and all he asked was that they would leave him (the speaker) Corot and Millet. A very excellent musical programme, in which the performers were Miss Winifred Clarke, Mr. R. D. Grant, Mr. T. B. Wright, and Mr. F. C. Tilney, interspersed the list of toasts. Mr. J. A. Sinclair proposed the toast of "The Society," in responding to which the Chairman presented, on behalf of the Society, a silver rose-bowl to Mr. Charles Beadle, retiring president, and a number of Autotype reproductions of works of art to Mr. Ainsley, who for six years had been treasurer. Mr. A. H. Lisett proposed "The Press," to which Mr. George E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY) responded. Mr. J. McIntosh gave the health of the visitors, to which Mr. W. Thomas replied. The toast of the artistes and producers of the menu were given by Mr. J. C. S. Mummary, and responded to by Mr. F. C. Tilney and Mr. H. Barnard, who spoke for Mr. S. H. Bently, by whom the photographic work of the menus had been done. Among the visitors were Mr. H. Chapman Jones, Mr. George Scammell, and Mr. A. Horsley Hinton. A most enjoyable evening was brought to a conclusion with "Auld Lang Syne."

THE Brin Oxygen Company have brought out an acetylene blow-pipe for working at very high temperatures, and applicable to autogeneous soldering of the more refractory metals. The blow-pipe is advanced as a substitute for brazing in iron and steel work of all kinds, and can be similarly employed in copper working. Although the high temperature of the flame would suggest its use for high-power limelight work, we learn from the company that this application has not yet been worked out by them. A prospectus of the blow-pipe and accessories is obtainable from the Brin Company, at Elverton Street, Westminster, S.W.

## Commercial & Legal Intelligence.

Is a Show Case a Building?—At the Chichester Petty Sessions last week several cases were heard in which infringement of the Corporation's bye-laws was alleged. Five summonses had been taken out, one of which was concerned a show case belonging to Mr. W. P. Marsh, photographer. The City Surveyor said the building in question was in front of a house now occupied by Mr. W. P. Marsh, photographer. It had the appearance of a detached shop front. It was 12ft. 5in. long, 4ft. deep, 6ft. high, with a fascia board at the top 1ft. 10in. deep, making a total height of 7ft. 10in. It was constructed of glass and wood, and had two doors at the rear. It was erected on seven posts. No plans in respect to this erection were received by him. Replying to further questions the Surveyor said he did not know whether the present structure was a box placed on top of posts. The height, 7ft. 10in., was from the ground to the top of the fascia board. He considered this to be a domestic building. Mr. Wannop (for the defence:) You wish to do away with all show cases unless built of brick?—This is not a show case, this is a shop front, it's a building. As a practical man you say this is not a show case?—It may be used as one but it is not one. Mr. Freeland: Do the neighbours object to this?—Yes. Have you had complaints?—My first inspection of this building was by reason of a complaint from a neighbour. Mr. Wannop submitted he had no case to answer. First there was no authority to prosecute because the resolution of the Committee had not been confirmed by the Council. He also submitted there was no proof of how the structure was fixed. It was absurd to say this was not a show case. It was a show case pure and simple, and how it could be construed to be a building he was absolutely at a loss to conceive. Mr. Wannop proceeded to read the report of a similar action taken by the London County Council, in which Mr. Paul Taylor, the magistrate, condemned very strongly the objection to such ornamental structures. Mr. Cooper: But supposing all the other houses were to do the same? A nice government we should have over our streets. Mr. Freeland inquired whether it would meet the case if Mr. Marsh would undertake to remove the structure when called upon. Mr. Bew, who held a watching brief for Mr. Marsh, said he had given his client certain advice, and he had information which would certainly not result in the removal of the show case. Defendant was next called to give evidence. The show case, he said, was made at his shop and taken bodily to Southgate, where it was placed on the platform and screwed into position to prevent it blowing over. It was a tenant's fixture. The whole thing could be shifted in five minutes, and four men could lift it over the fence. By Mr. Cooper: He did not look at the bye-laws when he received the order for the work, but he would certainly have done so if he had been asked to build a house. The Bench having retired in private, Dr. Paxton said they had considered the case very carefully, and had come to the conclusion that this was not a building within the meaning of the bye-laws. The case was accordingly dismissed, and the Town Clerk intimated that he withdrew all the other cases relating to the same property.

Re Benjamin Pearce, Liverpool House, Maengwyn Street, Llanynlleth, watchmaker and photographer.—The above-named debtor appeared for his public examination at the last sitting of the Merystwith County Court, before the Registrar. The statement of affairs filed by the debtor disclosed liabilities amounting to £80, and there was a deficiency of £74 9s. 6d. The causes of failure as alleged by the debtor were loss in consequence of forced sale of freehold land and studio by mortgagees on January 9, slackness of trade at Towyn, inconvenience in carrying on trade, the shop at Llanynlleth where he lived being a considerable distance away, lack of trade, and heavy household expenses. Bankrupt, aged forty-four, commenced business as watchmaker twenty-three years ago without capital, and had carried on business as photographer for the past twenty years. He kept no books of account, his trade was small and practically for ready money. Nearly the whole of the liabilities were for goods supplied. In reply to questions, debtor said the studio at Towyn sold for £200, which was enough to pay mortgage and costs. The business there was beginning to pay. He handed it over to his daughter, but she did not work it as she ought to have done. He had had a great deal to do

with volunteering, but when he went to camp he took his camera and made money. He had won cups for shooting, but had not won them outright. The examination was adjourned.

A COPYRIGHT CASE.—At the Bury County Court, last week, an action was brought by Mr. G. S. Cousins, photographer, of the Butter Market, against the Bury St. Edmund's Printing and Publishing Co., from whom he claimed £100 for infringement of copyright. The alleged infringement consisted of the publication of election buttons bearing a portrait of Captain Hervey, of which plaintiff held the copyright. The plaintiff was represented by Mr. H. O. C. Walpole, and the defendants by Mr. Henle. Mr. Cousins, it appeared, had photographed Captain Hervey at his residence on the request of a stationer named Pawsey, who wished to reproduce the Captain's photograph on an almanac. Mr. Cousins sent complimentary copies to Captain and Mrs. Hervey, and granted Pawsey the free use of it for his almanac. On December 16, 1905, he registered the copyright. Afterwards the photograph was reproduced in the form of photo-buttons and plaintiff also found that the portrait was being reproduced in an almanac of the "Bury Free Press." He obtained 10s. 6d. for permission for it to be there used, but that did not include the right to sell it as buttons, the sale of which still went on. It was finally agreed to accept £5 and £20 costs, the former sum having been paid into court by defendant.

A DEALER'S CASE.—At Liskeard County Court on Monday, William James Govett, photographer, St. Cleer, sued Messrs. Smedley and Co., photographic dealers, Fleming Square, Blackburn, for damage for delay in executing an order. Mr. A. W. Venning for plaintiff. Plaintiff stated that on October 20 he ordered a photographic accessory, for which he forwarded £3 19s. 9d., but up to the present he had not received the article. His Honour (Judge Granger) asked if plaintiff had a receipt for the money, and on plaintiff replying in the affirmative, gave judgment for the plaintiff.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### HALF-DAY CLOSING.

To the Editors.

Gentlemen,—Competition is the one word that answers Mr. Lang Sims' letter re the above. True, he implies if all combined to close their establishments it disposes of competition. Probably for the time being it does. But presume that it is done in some town by every established business. Some newcomer sees the opportunity and seizes it, opens a studio, and does all the work during that close season—of course, presuming his work is up to the town's standard. I, like Mr. Lang Sims, during my early experience, worked from 9 a.m. up to all hours of the night, often until midnight, because all the trimming, toning, and mounting—in fact, the general work—had to be done after tea, when the day's rush was over, such toning being done in six or seven table meat dishes, four or five prints in each dish only, so as they could all be seen. These reminiscences date back to the early sixties, when the full length carte-de-visite and the passe partouts were the rage, when all our female sitters wore crinolines and pork-pie hats, and the male gender peg-top trousers of a very assertive check pattern, when the streets resounded with the air of "Ole Bob Ridley, oh!" But I must check my thoughts and pen and deal with more recent events, say of fifteen or twenty years ago. At that time every studio in this town closed its doors and put up the shutters (shutters are now obsolete) at 6 or 7 o'clock, the owners going home to their suburban residences to enjoy their gardens in the summer and fireside in the winter, and some, to their credit, do it yet; but alien competition settled on the town. Studios were kept open for artificial light work, well-dressed windows were shutterless, and brightly lighted up as late as 10 and 11 o'clock every night of the week, and presents were given to every sitter who paid for a dozen cabinets. Hence the old-established studios, to use Mr. Lang Sims expression, "had to fall into line" and do likewise, and

it is even so up to the present day. Nay, worse, for Sunday work is openly carried on as well as in a covert fashion, but in this I do not "fall into line." I would prefer being maintained by the rate-payers. By the bye, it is common rumour that one of our well-known prominent retired photographers reached that happy (?) position by Sunday work many, many years ago, so it is nothing new. I do not pen these lines in animosity to any feasible scheme that could be devised to better our lot all round. I merely recount facts, but it is no use trying to keep the sea back with a broom. It is probably best to go with the tide, and occasionally drift into some quiet secluded pool for rest and enjoyment, or, in other words, take your holidays when you can after earning them. My employees each have a half-day off per week, half the staff on one day and half another, alternating the days or arranging among themselves to suit their varying requirements. Has any one a better scheme to propose which will not open a way for some one to assert their will in strenuous competition, for where there's a will there is a way, as Mr. Lang Sims quotes?—Yours faithfully,

The Studios,

7 and 8, Park Street, Anlaby Road, Hull.

W. BARRY.

#### To the Editors.

Gentlemen,—As an employee of many years experience, I wish to thank Mr. Lang Sims and others for their praiseworthy efforts to procure for us what every board-minded employer will admit is of vital necessity. Our work is tedious, exacting, and often nerve-destroying, while long confinement in small air-tight dark rooms has its terrible effect on the strongest constitution, and surely a few hours of sunshine and fresh air every week is not much to grant a fellow-being.—Yours faithfully,

FRANCIS B. WILLIAMS.

Sirdar Villa, Ryeland Street, Hereford.

#### To the Editors.

Gentlemen,—Your correspondent who styles himself "A Member of the P.P.A.," has given expression to the opinions of a number of assistants who, like myself, wish to raise the standard of professional photography.

I am not making a plea for lazy assistants, but I certainly think that it would be greatly to the advantage of the majority of employers if they adhered to the usual professional hours of 9 to 6. There are times when perhaps it would be necessary to take a sitter by artificial light, or to devote one evening a week to that kind of work, and no assistant would be so unreasonable as to object to this if his other evenings were free. In these days we get very little time for self-improvement. An assistant closing at 8 p.m. cannot be expected to attend a lecture, demonstration, or meeting of a photographic society beginning at that same hour, and as a general rule an operator is grateful if he can get a few moments to himself when he has been working with perhaps trying sitters from 9 a.m. to 8 p.m. But enough of this; it is sufficiently apparent to those employers whom it concerns, that low wages and little leisure time is not the way to improve the ability of assistants and the production of a studio.

BERTRAM T. HEWSON.

Elham, Canterbury.

March 20, 1906.

#### To the Editors.

Gentlemen,—I am interested in the letter on "Early Closing." I am now an employer, and I believe in consideration for those employed very greatly. I close my premises on Thursday at 1 o'clock, and I feel sure that I do not lose in any way. Indeed, I am assured by all my employees that they are very content, and would not wish to make a change, and I do not think that even the highest photographer in the land is better served than I am. I also find from personal experience that consideration in the matter of fires in the winter makes a lot of difference in the work. I have been in places where I simply could not retouch, because I was too cold, and therefore my employer lost a lot of work, whereas had I had a good fire I should have done three times as much. Probably if more employers had been through the mill as assistants they would show more consideration. I sincerely hope, in con-

clusion, that I shall never treat those working for me as I have sometimes been when in the employ of others.—Yours faithfully,

ALICE O. YARDLEY (an ex-assistant).

High Street, Gorleston, March 19.

#### To the Editors.

Gentlemen,—As one of the large class who would be much benefited by the general adoption of a half-holiday, may I be allowed to point out that those employers who are hesitating to adopt this system are really standing in their own light.

I work now from 9 till 6 nominally, and this practically means 6.30 by the time I have cleaned up generally, including myself. After this I have little inclination to do anything but lounge about in a chair and read light literature, and the only time I really devote to photography after hours is when I read the B.J. on a Friday night. I have no time for trying any new processes, nor have I the inclination, and in this your previous correspondent—"A Member of the P.P.A."—is perfectly correct and logical.

I know that after my Sunday's rest I am always fresher than any other day of the week, and look forward to the same most anxiously.

As regards the day of the week which should be chosen, this must always be a matter for each town to decide. With us it would be impossible to close on a Saturday, as we do more business then than any other day, but as the large drapers and some other establishments close on Wednesday, we might well have that half-day, as I find, on reference to our appointment book, this has been the quietest afternoon throughout the whole of the last twelve months.

With regard to the loss of business, it may be interesting to cite the case of a friend of mine, who is manager in a large chemist's close by. They invariably close on Wednesday, and he informs me that he has not been able to trace any loss through having adopted this plan. The chemist's business is, of course, different from ours, in that there must always be somebody ready in case of an emergency. But my friend informs me that after the first few weeks his customers soon got to know he was closed, and sometimes now he does not have even one visit between 2 p.m. and 10 p.m. on the half-holiday.

Surely what can be done by the chemist who supplies necessities can be adopted by the photographer who only deals in luxuries.

For obvious reasons, I withhold my name and address.

A CHIEF OPERATOR.

#### THE NON-RETURN OF SPECIMENS.

##### To the Editors.

Gentlemen,—In "Ex Cathedra," of March 16, 1906, the subject of specimens being delayed is again referred to. I also notice the assistant is asked to send the return postage for his specimens.

I should like to know the opinions of a few leading photographers on this subject; myself, I think that if the employer wants an assistant, and the assistant wants employment, which, I take it, is the object in view, why should not the assistant bear cost of postage to the employer, and the employer return them post free. Nothing, I think, could be more simple, or more fair to both.

There is a great need for some fixed rule in this matter, and I should be extremely obliged if a few photographers—preferably high-class portraitists—would give their opinion on the question. I ask this not for myself, as I shall not deviate from the rule I have adopted, but for hundreds of assistants who, I am sure, would wish the matter settled once and for all in the manner I have indicated.—Yours most sincerely

B. T. H.

##### To the Editors.

Gentlemen,—May I tell you of an experience that I had as an assistant as regards the return of specimens, as in this case the blame was very evidently not to be attached so much to the employer as it was to the employees then on his firm. I had answered to my advertisement asking me for particulars and specimens. I sent these with postage for return. My application was not accepted, but the specimens were not returned. I wrote, and still no reply. I wrote again, same result. So finally I sent a letter and wrote "Personal" on the envelope. Within a day or so I had a note from the gentleman with the specimens, apologising for not having sent them, and saying it was the first he knew of it.

should undoubtedly say that the first postcard and note that I sent were never seen by the head of the firm, and were simply put in the waste-paper basket by his clerks as not worth noticing. I have also lost other specimens in answering to a box number, and therefore carefully avoided answering them.—Yours,  
March 19, 1906.

EAST ANGLIAN.

#### COLOUR-PHOTOGRAPHY.

To the Editors.

Gentlemen,—With reference to your remarks of a fortnight since, regarding a permanent exhibition of photographs, may I say that, if you have any difficulty in getting some of the exhibitors to leave their exhibits for such an object, I could let you have one or two of different subjects, by three-colour carbon, and should consider it a distinct privilege to do so?

By the way, I shall only be too glad to form one of your suggested colour society. Perhaps you will enter my name in this connection to help to back up Mr. Butler's sensible suggestion.—Yours faithfully,  
HAROLD HOOD.

St. Bride Works, Middlesbrough.

March 16, 1906.

To the Editors.

Gentlemen,—Referring to Mr. Howard Farmer's excellent suggestion of making your collection of colour-photographs a permanent one, I do not doubt that most exhibitors will be glad of the opportunity to present some of their work, and in doing so express their appreciation of the convenience you so kindly offered to them to compare notes and to form an idea of the present state of colour-photography. The exhibition has been a great incentive to the exhibitors, and the deepest interest has been shown by professional, amateur, and general public alike, and I have positive proof that this interest has not been a passive one.

Mr. Farmer refers to payment for certain exhibits. Surely the fact that this experimental work, with all its imperfections, yet so very promising, is at all considered worth preserving should be taken as sufficient compensation by most exhibitors, especially if the number of exhibits is limited to not more than three. I hope that Mr. Farmer's proposition, which is seconded by the Editors of this journal, will meet with a response in keeping with Mr. Farmer's generous praise, and in tune with the progressive motives which induced the Editors to arrange for this unique exhibition. I need hardly add that I shall gladly offer my exhibits whenever requested to do so. I am, dear Sirs, your faithfully,  
HENRY O. KLEIN.  
Westcliff-on-Sea, Essex.

To the Editors.

Gentlemen,—Mr. Butler's letter in last week's issues states that this camera (Patent No. 4,290, 1905) works at an angle of 35 degs. If the drawing of Mr. Butler's patent in the "Almanac" is approximately correct, then we can take for the basis of calculation and verification the size of a photographic plate as one unit, and we can allow  $2\frac{1}{2}$  units for the focal length; otherwise, should we take a shorter focal length, the plate at "D" would stand in danger of being partly exposed to the direct rays from the lens. By this basis of our calculation the radius of  $2\frac{1}{2}$  units would give a diameter of five units and a circumference to the circle of 15.65, which will show at a glance that  $15\frac{1}{2}$  plate units are required to form a circle, or 360 degs., and so I come to the conclusion that the possible angle of view is maximum 23 degs.

If Mr. Butler can use ordinary glass as colour-filters, and especially as reflectors, he certainly affirms a new view of accurate theory.

I am sure this fencing round my statement, that three equal-sized pictures cannot be made by the now known "reflector system," will not prove the case, but to publish the facts without being safeguarded would not further my interests.

OTTO PFENNINGER.

Brighton, March 10, 1906.

[In reference to the negatives which Mr. Butler forwarded to us, (two sets of half plate negatives), there is not the slightest question as to their being critically sharp and possessing images of absolutely identical size. This is the more readily seen as one is fine, straight, and circular lines, which it is extremely easy to superimpose, and which would at once show want of definition and variation in the size of the images.—Eds., B.J.]

#### A COLOUR PHOTOGRAPHY SOCIETY.

To the Editors.

Gentlemen,—The suggestion made by a correspondent in your last issue with reference to the formation of a society, the object of which is for the mutual assistance of its members and the advancement of that exclusive and fascinating branch of our art science, tri-colour photography, will, I feel convinced, meet with the approval of all workers. Living in the provinces, I do not often come in contact with the work of other people in the above-named branch of work. Should such a society be formed, personally I should be pleased to become a member. No doubt the place of meeting would have to be in the metropolis, but the benefits to be derived by provincial workers might be in the form of a circulating portfolio of prints and a circulating set of slides; lectures and reports of the demonstrations, etc., could be printed in the form of a circular, and would prove a very valuable contribution to the advancement of that branch of photography which in the near future is bound to make a revolution in many trades and professions.

The universal application of this process to the various methods of reproduction at the present time is almost an accomplished fact, and alone is sufficient to show the importance of such a beautiful process, and the present time is very opportune to make and carry out the suggestion made by your correspondent. Two years ago only I gave several demonstrations of my methods of working before various societies connected with the Yorkshire Photographic Union, in which I ventured to remark we should before long find pictorial photographs with the additional charm of colour adorning the walls of our exhibitions. A pictorial worker universally known and a leader of pictorial workers took strong exception to my remarks at the time. I have recently wondered what he now thinks about the matter, if he has taken the trouble to visit your little exhibition in which I feel convinced were two or three exhibits quite sufficient to convince the most sceptical there are exceptional possibilities in the three-colour process practised to-day for picture-making, although only in its infancy, and I think I may venture further and say we shall see distinct advances in this direction at the forthcoming R.P.S. exhibition.—Yours truly,

F. W. PLEWS.

39, Belle Vue Avenue, Roundhay, Leeds, March 19, 1906.

To the Editors.

Gentlemen,—I think with you that if Mr. Butler's suggestion took the form of a postal club it would be of greater value to the greatest number of members. I should very much like to become one of the initial members of such a club if formed, and would be pleased to render any assistance in my power.—Yours faithfully,

HENRY J. COMLEY.

"The County Studio," 10, Russell Street, Stroud.

March 17, 1906.

[Several other correspondents write us to the same effect. We will deal with their letters in a later issue.—Eds. B.J.P.]

#### MEASURING SHUTTER SPEEDS.

To the Editors.

Gentlemen,—It was only yesterday that I came across your editorial in your issue of March 9, referring to my method of taking shutter speeds, which appeared in PHOTOGRAPHY of February 27, or I should have written in time for my reply to have appeared in your following issue.

You ask, in what part of swing of pendulum should the exposure be made?

The position, to be exact, is  $\frac{1}{10}$  ths of the distance from the starting point to the bottom of the swing, measured along the line which represents the "one second" exposure.

This  $\frac{1}{10}$  ths is somewhere between 1.5th and  $\frac{1}{4}$  gr. of that distance, and if the exposure were made at the former position the error in reading would be only 0.034 of a second too little; and if in the latter, 0.039 too much.

You will see, therefore, it is not absolutely necessary that the exposure should be made at this exact position.

On the other hand, if the exposure is made at the centre of the

swing, then the time of the shutter can be ascertained *exactly* by noting the following simple formula:— $E = \frac{L}{S} \times \frac{\pi}{2}$  where  $L$  is the measurement of the line (less its width) representing the full swing of the pendulum;  $S$ , the short line (less its width), representing the shutter exposure; and  $\pi$  is the relation of the diameter of a circle to its circumference (3.1416).

For another method of arriving at the exact measurement, I am indebted to a correspondent in last week's issue of "Photography," who gives a scale for measuring the exposure when taken in *any position of the swing*, and reading off its duration without calculation.

That the writer does *not* "ignore the law of velocity of the pendulum" is clear from the last paragraph of my letter to which you refer.

You are good enough to say the method cannot be accurate. I must refute such a statement, for the exposures can be worked out to any degree of accuracy that may be necessary, and the shutter speed be thereby accurately ascertained, and I assert that this can *not* be done by the ordinary means in use.

You say a certain amount of work is done in bending the flexible tube which will cause the velocity of the pendulum to vary—but as the power required to bend the tube is only  $\frac{1}{16}$  of an ounce, and the pendulum weighs 8 lbs., and whereas the average of the "bob" is six times that at the point where the tube is attached, it follows that the retardation caused by bending the tube is to the momentum of the pendulum as 1 to 30,000. From this it will be seen the objection you raise is reduced to an absurdity.

Further, you say,—the very primitive method of suspending the pendulum will disturb the velocity irregularly.

As a matter of fact, in the instrument I was using it did not. However, if my method of construction was primitive, and I do not, as an amateur, profess to be a mathematical instrument maker, then I fail to see that that, in itself, has anything whatever to do with the system.

Appearances may be misleading, otherwise one might, I fear, be led to suppose that you were labouring to condemn an invention likely to be of service to photographers, that appeared for the first time in a rival paper.—Your obedient servant,

ARTHUR A. WATKINS, A.M.I.C.E.

Bala Lodge, Blackheath, S.E.

March 14, 1906.

[We must repeat Mr. Watkins either ignores, or is ignorant, of the laws concerning the speed of a pendulum. The law is that the speed, which is zero at the commencement of a swing, gradually increases until it is a maximum at the mid-position, and then gradually decreases until, at the end of the swing, it is again zero. Thus at "the lowest point of the arc of motion" there is not "either a slight acceleration or retardation of the angular movement" as stated by our correspondent. In fact, it is the only point at which the acceleration, whether positive or negative, is zero. The law being as stated, we should expect the length of the line made by using the shutter to be longer, the nearer the exposure is made to the middle of the swing. Now, in the specimen exposure published by Mr. Watkins, there are two short streaks showing two exposures. One of these is distinctly longer than the other; it is also the one which is appreciably nearer to the middle of the streak representing the full swing. This then confirms our criticism.]

As quoted by us on March 9, Mr. Watkins directs that an exposure should not be made "when the bob is at the lowest point of the arc of movement." Now he writes that "the time of the shutter can be ascertained exactly" by using a formula, which certainly can do

nothing of the kind. (The correct formula being  $\frac{s-w}{2\theta\sqrt{2l}}$  where

$(s-w)$  is the length of the short line corrected for the width of the sun  $\theta$  = total angle of swing measured in circular measurement, and  $l$  is the length, in fact, of a simple pendulum swinging to same period as the compound pendulum used.)

Later in the above letter there is a paragraph which we confess we cannot understand. First, there is "the power" (work per unit time) which either causes or is compounded with (we are not quite sure) the "retardation"—(negative acceleration) being compared with the momentum (quantity of motion)—of the bob. Does Mr. Watkins mean *moment*? If so, then all we can say is that the length of the

pendulum (the "leverage" of Mr. Watkins) has nothing to do with the moment, causing the pendulum to vibrate. Indeed, our contention concerning the bending of the tube is far from being an absurdity.

As for the assumed uniformity for the movement of the pendulum, even if the pendulum does swing once in a second, it simply means that the average acceleration has been such as to cause the pendulum to complete a swing in this time; but it does not follow that the actual acceleration has not been altered by the varying friction which must result from so crude a method of suspension.—Eds., B.J.P.J.]

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- W. Bradbury, 387A, Limefield, Bury, Lancs. Photograph of a Hen Fostering a Litter of Pups.
- F. Watson, 35, Queen's Road, Bury St. Edmunds, Suffolk. Two Photographs of Old Staircase at the Shirhall, Bury St. Edmunds.
- A. T. Sidwell, Meriden, near Coventry. Two Photographs of Wroczal Abbey, Warwickshire.
- W. Boughton & Sons, 102, High Street, King's Lynn. Photograph of Nurses with the late Mr. F. H. Hand.
- C. Bellinger, 4, Town Hall Terrace, Paignton, Devon. Photograph of a Portion of Winner Street, Paignton, with Old Thatched Roof Houses now Demolished.
- A. Shaw, 32, Briardale Road, Seacombe, Cheshire. Photograph of the Wrecked Soreo Steamer "Fearless" in the River Mersey.
- Armoury-Sergt. J. P. Worral, Whittington Barracks, near Lichfield, Staffordshire. Photograph of Monument to Non-Commissioned Officers and Men of 2nd West Riding Regiment who Died at Dinapore and Barrackpore during 1904 and 1905, Situated at Military Cemetery, Dinapore, India.

**AEROGRAPH.**—Will you please inform me:—1. What sort of colour I must use with the "Aerograph" for carbons and bromides? Will the ordinary kind, diluted, do? Or are there special kinds made? 2. Can you tell me of a firm in Leeds who supply "busts" suitable for practising lighting on?—ROTARY.

1. The best are the pure artists tube colours. 2. We know none in Leeds. We gave the addresses of several in London in a recent issue.

**ARTISTIC LENSES.**—With reference to an article in the B.J.P. of March 9, on "Artistic Lenses," by Messrs. Puyo and de Pulligny (page 184), I should be much obliged if you could tell me or answer the following questions:—1. Is the "adjustable landscape" lens suitable for portraiture also? 2. Can the lenses be used in orthochromatic work? 3. Can they be used in architectural studies? 4. Also, please let me have the address of a firm which makes the lenses, and would supply them either mounted or unmounted.—K. KRALL.

1. It is so recommended by Major Puyo, but it has not the speed of the special portrait anachromats. 2. See our note last week in "Ex Cathedra." 3. At small apertures. 4. See our advertisement pages for the past three issues.

**STUDIO QUERY.**—Will you please give me the best measurements for a small studio to measure about 16ft. by 9ft., single or double roof, and the amount of glass. 2. Would a 1-1 Cooke lens f/8 be suitable?—MELTON.

The studio will be very small, if required for professional work. Either the ridge, or lean-to, form is good, but something will depend upon the situation as to which is the preferable. We should recommend you to get Bolas's book, "The Photographic Studio: A Guide to its Construction, etc.," published by Marion and Co., 2s. From that you will be able to see the form that will best suit your place. 2. The

lens mentioned could be used, but, in so short a studio, it would not do for full-length standing figures. It is also much slower in action than ordinary portrait lenses requiring about four times the exposure.

COUNTRYMAN.—We are sorry, but we do not know the actual makers.

ISTO.—As a rule, the mounts are ordered to the sizes of the prints, but you could mount on plain board, and then use one of the commercial mount cutters, which can be obtained from any dealer.

SUBSCRIBER.—1. You will find two or three firms advertising the lenses in our advertisement pages, and application should be made to them. 2. The trouble can be got over by lining your roof with some non-conducting absorbent material such as thin felt, Willesden canvas, or compo board made by the British Compo Board Company, 18, Roscoe Street, Golden Lane, London.

OMIDE PRINTS, ETC.—1. Are bromide prints (black and sepia toned) permanent, if treated carefully and properly, according to instruction? 2. What focus should a lens be for a studio 20ft. long?—DOUBTFUL.

1. Certainly. 2. It is impossible to answer this without knowing the size of plate, etc. If our correspondent will refer to p. 1124 of the "Almanac" for 1906 he will find a table of working distances for a given sized image, and he will thus be able to find which would be the most useful focus.

NERST LAMP.—1. Is the Nernst light equal in candle-power to an ordinary blow-through jet when used in an enlarging lantern? 2. Are there any particular disadvantages in the use of the Nernst light for this purpose?—NERNST.

1. We believe the lamps can be obtained equal in candle-power to an ordinary blow-through jet, and R. W. Paul, 68, High Holborn, W.C., would send you details. 2. The only disadvantage is that the filaments show on the paper. It is therefore necessary to use a diffusing screen of ground glass between lamp and condenser.

VER PAPER.—You recently had an article in the BRITISH JOURNAL on silver prints; would you kindly tell me the number, as I have mislaid it?—H. G. LUCK.

Probably you mean the articles on plain paper in last year's issues, April 28, May 12, May 19, and June 2. If your query refers to albumen paper the references are June 16, July 21, August 11, and August 25.

RIGHT.—A short time ago I secured some fairly good negatives of a prominent part of our town. Since taking the photographs the most imposing building has been destroyed by fire. The negatives taken were on my own account and for my own use, but I did not have the same copyrighted, as perhaps I ought to. I was somewhat surprised, however, to see in a stationer's window reproductions in postcards from my photographs. No one ever asked my permission to reproduce them, and, of course, I never had a penny for it. (1) Can I take proceedings against the publishers? (2) Can I now have my photographs copyright and stop a further sale? (3) What would you do in such a case?—W. J. B.

(1) You have no remedy for infringement before registration. (2) Yes. (3) Register the copyright at once.

T-ALBUMEN PAPER.—I see there is in the market some matt-albumen paper, different textures. As I sensitise my own ordinary albumen paper would it be possible to procure also matt paper for the purpose, and could you recommend a medium, strong, and rough cheap one? And how would you prepare for sensitising?—MATT ALBUMEN.

We do not know of any unsensitised matt-albumen paper being on the market. The earliest albumen paper used had little more than a matt surface. The formula for that was: Albumen, 20 oz.; water, 20 oz.; chloride of ammonium, 400 grains. Beat up into a perfect froth, allow to subside, and pour off the clear portion. Float the paper upon it, and, when dry, sensitise on a sixty grain solution of nitrate of silver. If less gloss than this gives is desired, use less albumen and more water.

PROPLATINITE.—(1) How should I make a stock solution of chloroplatinite of potassium? Some time since I mixed up a fifteen

grain tube, with water, and in a few days it greatly discoloured. Should I add a few grains of acid to the water to make the solution keep? I require it for making a toning bath for collodion paper. (2) I sometimes want to make small glass cutting shapes for trimming prints. I find the edges of the glass rather too rough. How would be the best way for me to grind the edges?—SEASIDE.

(1) Use distilled water and add a drop of pure hydrochloric acid. (2) The very finest emery powder, obtained by allowing the commercial powder to deposit its coarse particles in water, pouring off the liquid with the finer in suspension, and allowing these to settle in time.

LENSES FOR GROUPS IN AN ORDINARY ROOM.—We are often called upon to photograph wedding and other groups, varying in numbers of three to twenty, at the residence of the parties, or at an hotel, in some room of the house. We shall be glad if you will kindly say which you consider the most suitable form of lens to use for such purposes, taking into consideration the light of an ordinary room and distance at disposal. We have been using Dallmeyer's D. Lenses for this work, but for 12 x 10 sizes a 5 or 6 D. would be required for covering purposes; these sizes we find large and cumbersome. R.R. Lenses are too slow for indoors.—W. H. M. & Co.

The lens we would suggest for the purpose would be one of the No. 11 series of stigmatics, by the same maker as those you have. They have greater covering power in proportion to their focal strength than have those of the "D" series, and work at the same aperture. They have also a flat field, with even illumination all over the plate.

A BUSINESS MATTER.—I am in business as a photographer and dealer in photographic goods. A neighbour of mine in the same block of buildings, and under the same landlord, is a dealer in sweets and fancy goods, including stationery. By our respective agreements we are neither to introduce anything into our business that will clash with the business of the other. We both wish to sell pictorial postcards. I should esteem it greatly if you would kindly inform me as to what extent I may legally go in this line, whether I must confine my sale of cards to photographic work alone, P.O.P., bromide, etc., or whether I may continue to print my own half-tone work, as I am accustomed to do?—POSTCARD.

Without seeing the agreements it is difficult to say definitely. We do not see that if you only sold your own work as postcards it would interfere with the business of the stationery; but if you sold picture postcards, such as come within his legitimate business as a stationer, it certainly would. Cannot you and the stationer come to some mutual arrangement on the subject, without going into the legal part of the question? It might be to your mutual advantage to do so.

RETOUCHING.—Will you kindly give me your opinion as to how many negatives, similar to enclosed photograph, a West-End firm could expect to be retouched (in first-class style) in a day of eight hours?—A. V.

Six to eight per day.

EMANATIONS FROM DARK SLIDES.—I have some 1-1 dark slides, which gave me a lot of trouble last year, because, when plates were left in for any time, the emanations from the front of the slide caused the negative to be of uneven density. I could not for some time discover the cause, and thought that the plates were stale (Ilford Chromatic), but have since found out the reason. Is there any remedy? I was thinking that I might cover the inside of the slide with tinfoil and then blacken it, or would it do to close the pores of the wood with French polish, or perhaps by this summer the wood will be older and not so liable to affect the plates, as it was only in the warm bright weather that it occurred? I shall be glad of your advice.—O. E. CHALLIS.

We fear that you will not be very successful in remedying the trouble with tinfoil, as we imagine you will find a difficulty in getting it to adhere firmly to the shutters when in use. We should recommend you to try filling up the pores of the wood with French polish, to which a little drop-black has been added. As the wood has become better seasoned by this time that will probably remedy the evil. If it does not, you had better return the slides to the maker to fit fresh shutters to them.

**BOOKS ON HALF-TONE.**—A correspondent writes, in reference to our reply in last week to a query asking for a book on half-tone, to the effect that the "Photo-Mechanical Processes," by W. T. Wilkinson, published by Hampton and Co., might also have been named. It was not by intention that we omitted to couple Mr. Wilkinson's book, which we recognise as an excellent one, with that of Verlasser.

A. N. G. (New York).—In our next.

J. T.—Have you made a second application or inquired dates of payment? After doing so, you might, if necessary, put the matter in the hands of a commercial agency, such as Stubbs, 42, Gresham Street, E.C.

**COPYING PLANS.**—I should be much obliged if you could tell me of some accurate method of determining and adjusting the error in parallelism of plate and plan board and ditto for verticality of axis of lens to both planes? I have experienced some difficulty in getting the outside portions of plate accurately to scale, the error being greater than that due to lens corrections. I am speaking of 30in. plates in map reproduction.—CHATHAM.

An accurate method is as follows (Abney):—On the centre of the easel a small mirror is fixed, strictly parallel to the surface of the easel. The point corresponding to the centre of the lens should be accurately marked on the ground glass. On the lens itself an open cap should be fitted, furnished with two cross wires, intersecting on the prolongation of the axis of the lens. The image of these cross threads will be reflected by the mirror, and should be focussed. The board should then be tilted or slewed round till the image of their intersection connects with the point marked on the ground glass.

CHAS. D. RUSSELL.—The chief fault is the want of covering power in the two bottom corners. The lens, no doubt, was raised, but is not equal to covering a much larger plate. The definition generally is not good, and though the conditions of making the photograph may have been partly responsible for this, we think greater sharpness should have been obtained. Decidedly a better lens is wanted for such work.

**SPOTS ON NEGATIVES.**—1. Can you please furnish me with a formula for an acid fixing bath, containing hydrochloric acid? I have had lately many small opaque spots in my negatives, the same occurring in all makes of plates I have tried. I am told the spots are caused by traces of iron in the water either in developer or fixing bath. Our water here is extremely soft, and it is only during the last few months that I have had this trouble, my methods being exactly the same during the last three years. I have found that a weak solution of HCl effectually remove the spots, hence my query. The trouble occurs whether I use the ordinary acid hypo or plain hypo baths. I am sending a negative, which you may destroy after inspection, to give you a better idea of what I am troubled with. 2. I am not a chemist, but if you could give a simple test for iron, I might test the water here.—S. HALL DOWNING.

1. It would be no use for us to give you a formula for such a bath, because you cannot have free acid in the hypo bath without decomposing the hypo and running the risks of imperfect fixation and stains. You can take other measures, however. Filter your water through flannel tied over the tap or with one of the filters (stuffed with cotton wool) sold for the purpose, or you can give the negative a bath of salt before development, washing it afterwards, but if you filter the water used for developing solutions you should not need the salt. 2. Place a few ounces of the water in a white basin, and add a few drops of pure sodium sulphide solution. A dark colouration appearing after, say, 15 minutes, indicates iron or lead. If it is produced, test a similar lot with potass ferrocyanide, which will give a blue colour with iron. The first test is the more delicate.

J. P. (Morden).—Why not use the glossy cards as supplied by the makers?

**APPRENTICE'S INDENTURES.**—Will you please let me know if my master can keep my indentures. I have served my apprenticeship, and now he will not give them to me, as I am going to work for another photographer close to him. My master

had no premium with me, and made out the indentures himself and paid the half-crown for the stamp. He says I can have them if I pay him the 2s. 6d. Can he force me to do that?—MARTIN.

It is usual for the apprentice to be handed his indentures when he has completed his term. We think, though we are not sure on the point, he is legally entitled to them. However, we should advise you to apply to the magistrate presiding at the police court of your district. He will tell you and if you are will see that you have them. Magistrates are empowered to adjudicate in all disputes between masters and apprentices.

**BUSINESS QUERIES.**—1. In your issue of the 16th inst., on p. 218 you give the tenders for the London County Council photographic work. Could you say what size of plate is to be used? 2. Some time ago I was in North Wales taking photographs for postcard work. While at Bangor I was approached by a stationer and bookseller, and ultimately took six views for him to select from. I sent him proofs, and he selected four. Finished copies, together with the account, were sent him. Since then I have had no word from him at all, although the account has been sent in every month. I shall be obliged if you will let me know whether, as the amount is under £2, I can sue him in the county court here or whether, in case he defended, it would have to be at Bangor. In the latter case it would cost me more to get the account than the account is worth. He got the photos from me with the view of having half-tone blocks made and publishing postcards. If he has published them and not paid for the original photos, could in any way, if I were to copyright the views now, sue him for infringement of copyright?—HARTLAND.

1. We have no information. In all probability various sizes are required, but we have not heard that they, or an average, have been specified. 2. You can sue him in the county court and the case will be heard in your town. You cannot register copyrights, because the photographs were taken to your customer's order, and are his copyright, even though he has not yet paid for them. See the article "Photographs unprotected" in the "Almanac," p. 674.

**RETOUCHER.**—We are not quite clear as to whether you want to soften the film or harden it. In the former case use a mixture of glacial acetic acid and methylated spirit, only be careful when using this, as it will in time completely dissolve the film. If you want to harden the film, then we should advise the use of a mixture of formaline and methylated spirit.

CLAUDE NORMAN.—Better ask Messrs. Penrose to put you on the employment bureau, or try a small advertisement in our own columns, or those of the "Photo-Engravers Monthly."

**FOREIGN JOURNALS.**—I shall esteem it a favour if you can give me the addresses of the leading American journals of photography, also French ditto. Can I procure same in England?—SISALA.

You will see the full list in the "Almanac" on pages 870 and 873. Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., could get any of them for you.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Formulae for focussing screens for ordinary, architectural, and aerial work are given in form adapted for home manufacture. (P. 243.)

The blistering of toned bromides is found to be preventable by proper precautions in the temperature of the baths. A contributor mentions the presence of traces of hypo. as the cause of markings on old bromides. (P. 243.)

The sensitising action of homocoll in admixture with pinacyanol or aniline is advanced by M. Monpillard for red-sensitiveness. (P. 245.)

Formulae for pinatype printing in monochrome from ordinary negatives have been published by Dr. König. (P. 246.)

The tanning action of pyro. developer upon gelatine has been examined by the Lumière brothers, who ascribe it to the oxidation of the pyro, by the liberated bromide to form a compound which, in the presence of sulphite, exerts a tanning action on the gelatine. (P. 245.)

German writer recommends Raffaelli's solid colours for coloured enlargements. (P. 244.)

View of the rising price of copper, photo-engravers are advised to the economies of the stripping process for half-tone. (P. 252.)

Among patents of the week is a system of stereoscopic projection. (P. 253.)

The Professional Photographers' Society of New York has published a list of twenty pressing questions to be discussed at its next meeting. (P. 250.)

A system of artificial lighting by reflection is recommended by a German photographer. (P. 249.)

The Birmingham Society are to provide the next house exhibition at the R.P.S. (P. 255.)

## EX CATHEDRA.

**Reflectors in Artificial Light Portraiture.** Mention was made in the article which we published in our issue of March 2 on the use of enclosed arc-lamps in photography, of the necessity for carefully screening the lens from any glare of light from the lamp or the diffusing media surrounding the lamp. It sometimes happens, more particularly perhaps when lighting what are called Rembrandt portraits, that if the reflector used for illuminating the shadows is placed at the shadow side or even almost up to the lens, an effect of cross-lighting is obtained. By using a reflector with a hole in it, through which the lens points, the effect of cross-lighting is avoided and the reflector forms a most efficient lens shade. The reflector should be so mounted that the hole, which may be rectangular and about the size of a half-plate, may be brought opposite the lens, whether the camera is raised or lowered. It will occur to every practical photographer that the back of the screen should be covered with black velvet and the edges of the opening bound with the same material. The idea was originally that of Mr. Van der Weyde, the pioneer in electric lighting. It has, of course, been used in copying, a black material being used to prevent reflection instead of the light material to produce it in the case of portraiture.

**Pictures of London.** Many of our readers who have seen our references to the work of Mr. Alvin Langdon Coburn, at present on view at the R.P.S. house in Russell Square, will have regretted that the distance at which they live from the metropolis prevents their seeing the remarkable collection of work. Some few of Mr. Coburn's pictures have been reproduced in the various photographic journals, but a further opportunity of studying the characteristics of his work is afforded by the inclusion in the April issue of the "Pall Mall Magazine" of six pictures which have been reproduced under Mr. Coburn's personal supervision. This issue should not only provide good examples of modern pictorial photography, but, in addition, be most interesting as indicating how London appeals to the possessor of an artistic temperament who comes to it as the Londoner, say, goes to Venice, Rome, or Madrid. As the "Pall Mall Magazine" says: "There are a thousand difficulties in the way of a true presentment of the charms of London by means of the camera—difficulties of light, of crowds, of never-ending change. It has been left for a gifted young American to bring a quick eye to bear upon this ever-tempting theme." Mr. Coburn's impulse, according to George Bernard Shaw, is always to convey a mood, and we recommend our readers to see the April issue of the "Pall Mall Magazine" and to study Mr. Coburn's work with this idea in their mind, that the pictures are not records of bricks

or weather vanes, but successful attempts at conveying some idea of the spirit of the great metropolis.

### Three-Colour Natural-History Photography.

\* \* \* The student of natural history by photography has shown himself in numerous instances the most enterprising and the most patient of photographers, as witness the heroic methods of the Kearsons and the telephoto work of Mr. Pike and Mr. Lodge. The next step apparently for the naturalist photographer to take is to colour photography in the field—collectors such as Dr. Hutchinson have utilised the three-colour process—but we have not heard that any general application of the three-colour process has yet proved possible in the case of the living subject. The possibility has, however, been demonstrated at lectures on insect mimicry by Mr. F. Enoch, F.L.S., by whom the assimilation in colour of larvæ and moths to their surroundings was illustrated by a series of three colour slides. An interesting example of Nature's protective measures was recently shown in the behaviour of the caterpillars of the pepper-and-salt moth. When placed on a lime tree they were of greenish-red colour, but when transferred to a laburnum assumed the silvery green tint of their surrounding. Mr. Enoch was optimistic enough to prophesy the practicability of an instantaneous three-colour process in the near future, but he had already showed the invaluable use which naturalists would make of it.

### The National Physical Laboratory.

\* \* \* The annual report which has just been presented shows the increasing industrial importance of the work carried out by the National Physical Laboratory. The fact that physical and electrical sciences are the chief fields in which the labours of the laboratory staff are prosecuted is a sufficient reason for abstaining from a precise review, but it may be mentioned that in the optical department of Bushey House investigations have been continued on standards of light with a view to ascertain the relation between the light standards used in America, Germany, and this country. It is also proposed to improve the methods of examining photographic lenses, though, if we remember rightly, nothing has been done in this direction since the last issue of the last annual report. The laboratory, however, must apply its staff to the demands made upon it, and we see that only eight photographic lenses were sent in for testing during 1905. The optical department also hopes to complete arrangements for the determination of the absorption of neutral and coloured glasses and for the measurement of shutter speeds. In these, as in other branches of its work, the laboratory has been lamentably hampered for lack of funds, but it is satisfactory to find that appropriate grants are likely to be forthcoming from the Government. Such scientific work as that the laboratory is doing has been fully recognised in America and Germany, where analogous institutions receive five and ten times respectively the sum for capital expenditure granted to the National Physical Laboratory.

### The Royal Society of British Artists.

\* \* \* One of the oldest exhibiting societies in London is the Royal Society of British Artists, which on Saturday last held a private view of its coming summer exhibition. Under the régime of Whistler this society enjoyed its palmy days. More recently it did not maintain the same high standard, but quite latterly it seems to have arrived at years of discretion, and is at present mounting again in the opinion of the art world. New members have now to gain their entrance strictly upon the

merits of their work, and they find the ordeal a severe one. It follows that the virility of the society must be looked for in the new blood, and also that as those occasional older members who, having dropped in, as it were, whilst the critical faculty was dozing, drop out again, the average of the work will continue to rise. There is plenty of room for this yet. Amongst the latest additions to the roll of membership the names of Miss Dorothea Sharp and Mr. Frank H. Swinstead are attached to works that display a genuine feeling for landscape, and give promise of poetic work in store for us. Pictorial photographers will delight, also, in the romantic work of Alec Carruthers Gould and D. Murray Smith, and will endorse the truth and charm of the mammoth water-colour seascapes of E. Gouldsmith.

### Art and Business.

\* \* \* A glimpse of the success which waits on the association in a photographic business of a photographer who is an artist to the finger tips with a partner possessing keen business instincts is afforded in the April issue of "The Photographic Monthly," which publishes an illustrated account of the methods and establishment of the Speaight studio in Bond Street. The phenomenal strides which the business has made are due to the supremacy of the brothers Speaight in their separate departments. The two together have established a studio which is a model of the best taste and a palace of ease and comfort besides. In the studio Mr. Richard Speaight's personality is responsible for the success of Speaight, Limited, as photographers of children, yet it is easy to imagine the qualities which have achieved the firm's artistic success thrown away under less adroit stage management. The business has struck a note of such dignity in photographic studios that we imagine many of our readers will peruse both the text and illustrations wherein Messrs. Speaight have, in a measure, taken the editors of our contemporary into their confidence.

### FINE FOCUSING SCREENS.

THE least satisfactory part of the modern camera is, perhaps, the focussing screen. It is invariably of ground glass, and yet the best ground surface is often much too coarse to allow of really critical focussing. The defect is not always felt, for it is only in certain circumstances that the need for a finer surface arises, but when those circumstances exist the need is a very real one. The usual remedy is a clear glass screen used with a magnifying eyepiece focussed on the inner surface, but this is not a very convenient remedy. Considerable difficulty is at first felt in controlling the accommodation, for the eye will quite readily focus itself upon the real image, even when that image is some way in front of the focussing surface. This difficulty can be got over by marking or scratching the front surface of the screen, but it is even then not altogether easy to keep the scratch and the image in focus at the same time. If both eyes are kept open the trouble is diminished, but we have found that even after long practice it is very easy to make mistakes; hence, while the value of a clear glass focussing screen is undoubted, we should always hesitate to recommend its use to the average photographer.

An expedient often advocated is the use of a barium sulphate screen. This is made by fixing an unexposed plate, washing it well, and then soaking it in a solution of sulphuric acid for a few minutes. After a slight rinse it is immersed in a solution of barium chloride, which produces a precipitate of insoluble white barium sulphate in

gelatine. When washed and dried the screen is finished, but our experience of such screens is that they are not very satisfactory substitutes for ground glass. They are finer grain, but still not fine enough to be free from the defects of the glass. Moreover, it is not always easy to produce an evenly distributed precipitate, while very often the deposit is too dense. Perhaps the best way of producing a barium screen is to coat a glass plate with an emulsion of barium sulphate. A fairly good fine grain screen is produced if a little barium chloride solution is added to a gelatine solution. The gelatine commonly contains enough sulphuric acid to produce a precipitate of barium sulphate, but it is not easy to control the density of the result.

Another way of making a screen that is often advocated is to fog a plate by exposure, and develop and fix it. The plate is then either used in this condition, or after the deposit has been bleached with mercury chloride. The effect of this method is that it is not exactly easy to produce the right amount or kind of fog by exposure. The result is generally uneven and often too dense, while the grain resulting from exposure and development is somewhatarser than is quite desirable. A modification of this method has, however, produced most satisfactory results in our hands. A very fine grain and even deposit is very easily secured by fogging an unexposed plate in a developer, and the density of the deposit can be controlled by varying the time of development.

Take three extra rapid plates and immerse them without exposure at all in any non-staining developer free from bromide. At the end of five minutes remove two plates and fix and wash them in the usual way. At the end of twenty minutes remove the third plate from the developer, and fix and wash that also. Next iodise this third plate together with one of the others in a solution of iodine in potassium iodide. When the action is complete, rinse the plates and bleach them in dilute ammonia. Then wash and dry. Finally, take the remaining plate and immerse it in a solution containing 10 grains potassium bichromate and an ounce of hydrochloric acid to every ounce. When the bleaching action is complete, rinse the plate and put it in a fresh plain hypo fixing bath for ten minutes; then wash well and dry. You now have three screens of different degrees of density. No. 1 is a dense iodide screen,

No. 2 a thin iodide screen, and No. 3 a thin "chromium screen."

No. 1 screen will be an excellent substitute for the ground glass in all ordinary work. It can be used without a magnifier or with one, and in either case it will show detail that would not be visible on a screen of ground glass.

No. 2 (the thin iodide screen) cannot well be used without a magnifier, but while it is too nearly transparent to permit focussing with the eye alone, it shows enough grain to render the use of the magnifier easy. There is no accommodation difficulty, and the detail visible on the screen is a revelation to those who have never used anything but ground glass. This screen is of special value for indoor work, such as architectural interiors and copying.

No. 3 (the chromium screen) is quite useless without a magnifier, being almost transparent to the eye. But with the magnifier a very fine grain becomes visible, and as it is perfectly easy to keep this grain and the image in focus at the same time there is no accommodation difficulty. This screen is a substitute for clear glass, and is especially adapted for copying and for low power photomicrography. For high power work it does not seem possible to find any good substitute for clear glass, but with moderate powers the No. 3 screen seems to show almost as much detail as the clear glass, while it has not its disadvantages.

In our own work we have dropped the use of ground glass altogether, and use No. 1 and No. 3 screens exclusively. Others have given the preference to No. 2 screen and use that as an alternative to ground glass, but the practical value of all three screens has been very thoroughly proved in actual work, and we can confidently recommend them. The screens can be ruled in pencil or with fine cuts to give datum marks. We prefer a cross ruling of fine cuts made with a lancet, but this is only a matter of personal choice. If the cuts are adopted it is as well to give the screen an after coating of celluloid varnish. The surface is somewhat readily abraded in the case of No. 2 and No. 3 screens, hence they should be carefully used.

It must be remembered that no fine grain screen shows such a bright image as ground glass. In comparison the image looks dull, but this is a very minor matter, and the extra detail visible far more than compensates for the loss of brightness.

## BLISTERS AND MARKING IN BROMIDE TONING.

The operation of toning bromide prints, etc., has almost reached the stage when we may say that it is as easy to tone a batch of bromides as a corresponding number of P.O.P. prints. For this we have to thank several ardent bromide experts, whose efforts have not always brought them appreciation, most likely because results were shown in the early days rather too hastily, when the tones produced were mainly colour, but somewhat fearful—if wonderful. Nowadays, of course, that is altered. The experimental stage has been passed, and bromide toning has become an everyday operation.

### Blistering During Toning.

On one respect, however, where numbers have to be treated, there is rather too much uncertainty about the final results. The prints are got easily enough, but how are we to insure against blisters and uneven toning. Not such a difficult matter from the point of view of the amateur, but professionally I must confess that calls for a great deal of thought and care and method. That the trouble is real is evidenced by the fact of the extra charge, sometimes ten per cent., for toning; at first sight this seems more than ample, so far as the writer's experience goes, it is not so.

### One Preventative—Constant Temperature.

Blisters, for instance, may come at times like an epidemic, and formaline baths do not invariably act as a safeguard. Al-

though in my practice we always use a formaline bath, the only real safeguard against blisters is an even temperature of the solutions and washing water. My workrooms are heated with hot-air pipes, which run under the sinks and are near enough to the waterpipes to keep the water supply approximately 50 degrees F. all through the winter. Constant attention is required to keep the rooms at 55 degrees or 60 degrees F., which is a comfortable temperature to work in. Hot-air pipes are very nice physically, but they may easily be overdone; in fact, with them it is practically one person's work to keep the rooms at a fairly uniform temperature throughout the day.

Much may be done by making all fixing baths one or two days before required for use. The solution stands in a jar in the room in which it is used for at least twenty-four hours before it is required and is usually only a degree or two below normal. After the fixing bath proper, transference to a similar bath of half-strength is advisable, thence to washing water, which is of average temperature. Much handling of the prints in a moderate-sized deep dish—say 12 by 10—soon brings a rise in the thermometer; one of those instruments should always be at hand for frequent testing. Washing in running water is, I think, hardly necessary; several changes will be safer and as effective. A sieve of very coarse mesh is useful to save much handling of the prints. These may be rinsed and drained very thoroughly in a utensil of the kind. Alum, or formaline, as a

'hardening' bath is invariably used before and after toning, and this operation carried through successfully, no time is lost in getting the day's output safely on the drying boards.

#### A Remedy for Blistered Prints.

Blisters, luckily, dry up sometimes so that the print, if to be mounted, is not wasted, but one cannot conscientiously send out blistered unmounted prints. Even in the mounting, as the blistered film is detached from the paper support, one has to be very sure that—in the mounting—it is quite secured again. The only genuine satisfaction we can get in the treatment of blisters is when they appear on the white margins of vignettied pictures; when mounted and quite dry very fine sandpaper deftly applied quickly obliterates all trace of the trouble.

#### Markings in Relation to Freedom from Hypo.

Then, again, marks of various unshapely outline appear now and then during the toning, in a manner difficult to account for. It is sound advice to remove all the hypo used in fixing by proper washing. It is not an easy thing to do if its total elimination is essential to a perfectly toned print. A developed print may be plunged into a fixing bath and allowed to remain for twenty minutes or so, but it may not be properly fixed unless occasionally moved and turned over during that period. Similarly in the washing stage it is not enough to place them in a dish of running water, even for several hours, unless they are frequently moved and re-arranged during the time. Markings on the prints—uneven toning, and so on—will usually be the result of allowing prints to lie undisturbed and forgotten, and this, unless one is constantly watchful, occurs not only during the fixing, but the washing period. When making enlargements the prints are transferred, after adequate fixing, to a large dish supplied with running water; the first lot put in will have perhaps twenty minutes' washing when the second batch will be plunged in on the top of the first. This may go on during the morning, and some of the first prints will be little nearer the washed stage after three or four hours than they were at the first. In any case, markings from splashes of hypo solution are inevitable. Obviously the first lot

should be moved to clean water and a fresh dish before removing from the fixing bath the second and subsequent batches. If the first few minutes' washing be thorough, half the work is done. This, I think, is a point generally agreed upon.

Only a few hours since I toned twelve prints. Nine of them had received a very short washing, the other three had been in water five hours. The nine toned up quickly and evenly and dried without markings. Two out of the remainder had marks upon them. The nine could not, as the result of such a short washing, have been entirely freed from hypo, and the toning, though rapid to a certain point, did not advance much further than the purple stage. My conclusion was that a trace of hypo might be left in the film and would not spoil the results, provided that the trace was evenly distributed; but from the nature of the deposit in or on the film—the result presumably of the presence of a trace of hypo—the operation would not suit all prints. There is no actual stain, but the shadows are not so pure and transparent as with a print from which all trace of hypo has been removed.

The above remarks refer almost entirely to the "copper toning bath." With the ferricyanide and potash bromide bath (alkaline), and browned with sodium sulphide, I have experienced no blistering, but the abominable odour entirely or practically bars the use of this. With copper, however, the toning is so easy and certain, and the colours so pleasing and satisfactory, that we should certainly continue using it, risking the blisters, but taking all precautions. I may remark here that a bath of methylated spirit has not in my hands been altogether successful, but—if time can be spared—an additional safeguard is, if the prints have come well through the washing stage, to dry them and tone them as an after and detached operation. Of course, a little time is saved by trimming them before toning.

It was a common thing twenty-five years ago for the dry-plate worker to be sneered at as being little better than a mechanic. Whatever the facts may be in the matter of the modern dry plate, no one will deny that bromide toning, carried out with intelligence, is an operation, the results of which would have astonished the veterans of the wet-plate brigade.

"ELECTRIC."

## FOREIGN NOTES AND NEWS.

#### Painting Enlargements.

DUNKMAN, in the "Photographische Chronik," states that he has never obtained satisfactory results using water-colours or glazed colours for painting enlargements, as the photographic image always shows through and robs the colours of their brilliancy. Pastels are also unsatisfactory on the gelatine surface, and, whilst fairly broad masses can be put in, it is almost impossible to draw fine lines with them. The author strongly recommends the solid oil-colour pencils of Raffaelli, which can be sharpened to a fine point, so that the finest line can be drawn. They will take well on any surface, and in a few days will set as hard as ordinary oil colours. They have the brilliancy and luminosity of water-colours, without the troublesome glaze of oil-colours. The most delicate tints can be obtained by mixing over white, or by using one colour over another, and if treated with a brush dipped in turps, soft, glossy mixtures are obtained. Mistakes can be erased with a knife, and lights can be put on by the same means, and they will be found to answer all the requirements of the painter.

#### The International Congress on the Focal Plane Shutter.

The report on this subject just published recommends that every shutter should be tested for the speed of the blind on its release, and when the exposure is finished: and the mean speed should be then deduced. The difference may amount to 40 per cent., which is stated to be an advantage when a considerable amount of sky is included in the picture. If the speed of the blind is more than 2 to 3 metres per second distortion of the object is negligible. If the edges of the aperture are composed of material, it is not advisable to reduce the same below 1 millimetre. Variation of the distance between the blind and the plate affects the efficiency and the useful aperture, and the increase of the latter is approximately  $\frac{e}{f}$

$e$  being the distance between the blind and plate and  $f$  the extension of camera: in most cases this is about 2 mm., and is negligible. As regards efficiency Colonel Moessard gives the following formula:

$R = 1 - \frac{e^2}{af}$  in which  $a$  is the width of the blind aperture and  $f$  the diameter of the lens. In most cases, from a theoretical and mathematical point of view, when the distance is as stated above, the action on the efficiency is of no moment. Practically, on the contrary, the influence may be considerable as regards the quality of the negative. We may conceive, for example, that an aperture, the edges of which are brilliantly illuminated, may diffuse some of the light over the plate; to reduce this diffusion the distance must be decreased. M. Sigriste believes also in the production of a species of fog due to diffraction, which becomes greater the greater the distance between blind and plate. To calculate the speed it is only necessary (to obtain an approximately correct result) to divide the width of the slit in millimetres by the speed of the blind in metres per second.

The method suggested of testing the shutters is to use an opaque disc, pierced by six apertures, which should be rotated ten times in a second; an examination of the images of the apertures in the disc will give the speed of the shutter at various stages. The data recommended to be given with shutter should be the speed at the moment of release, and when the blind is down, in metres per second, the ratio of these two speeds and the mean speed. The maximum and minimum useful widths of the slit should be also given, the mean distance of the blind from the plate and the time of exposures for every 10 mm. slit width.

#### Dark Slide Shutters

Dr. Neuhaus points out in the "Photographische Rundschau" that aluminium dark slide shutters emit radiations which spoil the plates, and that varnishing does not prevent this action. The

inary ebonite shutters are permeable by violet and ultraviolet light, and they frequently give rise to electric markings. Wooden shutters are also transparent to sunlight, and fresh glue and varnish will also fog plates. From numerous experiments with ebonite and other metals the author strongly recommends brass for shutters—this neither emits nor transmits any rays whatever. In connection with this subject, we may point out that Professor Charkoff, of Charkow, has been investigating the peculiar radiations of metals, and finds that some metals emit rays which affect bromide like light, and that others restore it to its original condition. The former radiation he proposes to call "positive," and the latter "negative," and cadmium and zinc are positive, and platinum and tantalum negative, whilst copper and brass emit a neutral radiation, and mercury and gold none at all. When the plate is thoroughly dried by phosphorus pentachloride there is practically no radiation.

### Mixed Sensitisers.

M. Monpillard has been spectroscopically testing the sensitising action of a mixture of pinacyanol, or dicyanine and homococcol, and finds that with both much more even sensitiveness is obtained throughout the spectrum. The bath used was:—

Pinacyanol or dicyanine (1:1000 alcohol)...	5 ccs.
Homococcol (1:1000 alcohol) .....	5 ccs.
Liq. ammonia .....	0.1 ccs.
Distilled water .....	1,000 ccs.

The developer used was the acid amidol developer (see page 208), containing 0.25 per cent. of bromide. With dicyanine the sensitiveness extends to  $\lambda$  750, with pinacyanol to  $\lambda$  680, as shown in the

Pinacyanol and Homococcol.

Dicyanine and Homococcol.

diagrams herewith. It is stated that all the colours are equally sensitive, and that over-exposure was easily obtained with an orange negative, and it is hoped, says the editor of "Le Procédé," that the eternal under-exposure of the blue-printing negative in three-colour work has now been abolished.

### Spots on P.O.P. Prints.

R. E. Liesegang states in the current number of the "Photographisches Wochenblatt" that, having occasion to try and explain the cause of some spots on gelatine P.O.P. prints, it was found that the amidol had been spilt in the room and that this had blown about and settled on the prints. When prints of P.O.P. and bromide and gaslight papers were made and then fixed and well washed and dusted with amidol it was found that a black centre spot was caused, and then there was a white

ring round this of about 2 mm. radius, and then a brown ring of about 1 mm. width. In the white parts the silver was bleached, and this, according to Liesegang, is to be ascribed to the absorption of oxygen by the air, the giving up of the oxygen to the silver, and consequent bleaching of the latter; the brown ring is due to oxidised amidol. If hydroquinone be dusted on to a print then only white spots are caused, as the oxidation product of hydroquinone is not so dark.

### Focussing Line Drawings.

M. Clerc suggests in the current number of "Le Procédé" the following method for ensuring critical focussing with lenses of larger

aperture when reproducing line drawings. Cut from thin card a piece the exact size of one of the Waterhouse diaphragms, and, unscrewing one of the lenses, trace on the card its maximum

Red. Orange. Yellow. Green. Blue Indigo. Violet.

aperture; divide this into four equal parts and cut out the upper and lower segments, leaving them separated by a band equal to half the diameter of the lens. Then carefully blacken the stop, and insert in the lens. Every horizontal line will now be represented double, and the separation between them will be greater the greater the distance from the sharp focus. When the focus is absolutely obtained the double lines will superimpose and form one line.

### The Tanning of Gelatine by Pyro.

MM. Lumière and Seyewetz have been investigating the tanning action of pyro on gelatine, and point out that it is assumed that this is partly due to the silver, as the shadows of a pyro-developed negative remain soluble. A sheet of gelatine immersed for an hour in a 1 per cent. solution of pyro with 3 per cent. of sulphite and sodium carbonate was not tanned at all. A negative developed by

one of the non-tanning developers treated with the same solution was not tanned at all, it was only after three days' action that plain gelatine negatives became insoluble. They found that a plain 1 per cent. solution of pyro did not tan in a month; if 3 per cent. of anhydrous sodium carbonate was added the tanning was complete in two days; with the further addition of 3 per cent. sulphite the gelatine became insoluble after four days. When these experiments were repeated and the air excluded from the bottles there was no tanning action in a month, proving that the hardening action is due to the absorption of oxygen. Other developers treated in the same way also proved in some cases to tan. If a cold saturated solution of quinone was added to a solution of gelatine it rendered it, even in the absence of oxygen, quite insoluble, whilst hydroquinone had no such action; 20 parts of a 0.5 per cent. solution of quinone added to 100 parts of a 10 per cent. solution of gelatine rendered the same quite insoluble, and this solution may be used to harden negatives as well as formaline.

All developers in plain aqueous solution exert no tanning action on gelatine, nor when mixed with sodium carbonate, nor with sulphite and carbonate, if the air is excluded. The conclusion arrived at is that in the case of pyro it is oxidised by the bromide absorbed from the silver bromide, and that this oxidation product, which is formed in the presence of sulphite, renders gelatine insoluble. As regards the other developers, the reason why they do not tan is probably due to the fact that their oxidation products are easily reduced by the sulphite in the developer.

#### Further Applications of Pinatype.

In the current number of the "Photographische Mitteilungen" Dr. König suggests the following methods of further utilising the principle of pinatype. Coloured transparencies may be obtained by printing from a transparency on to bichromated gelatine plates, which may either be useless dry plates thoroughly fixed and washed and then sensitised in a 2 per cent. solution of bichromate, or glass may be coated with:—

Hard gelatine .....	240 grains.
Water .....	10 oz.
Potassium or ammonium bichromate.....	96 grains.

allowing from 68 to 84 minims to every 16 square inches. When dry, the plate should be exposed under a transparency, an actinometer being used to determine the duration of printing, though the speed

of the plates is about the same as P.O.P. After exposure, the plate should be well washed and then stained up in a 2 per cent. solution of a pinatype dye. These can be obtained in black-brown, olive green, bright green, dark blue, and also blue F and red F, these latter being the colours used for the pinatype three-colour process. As soon as the transparencies are sufficiently stained they may be either rinsed and dried, or else treated to a fixative bath of weak copper sulphate solution, and this gives a greater range of colours. The dyes are perfectly stable to light.

By squeegeeing these dyed plates on to gelatinised paper, which may be either of plain, matt or rough surface, the gelatine will absorb the dye, and the prints can hardly be distinguished from carbon prints.

Reversed negatives can also be made by printing from the original negative on to bichromated gelatine and then staining up after exposure and washing in the black-brown dye, which turns black when treated with the fixative. By printing from this reversed negative again another correct negative is obtained, so that by under or over exposure it would be possible to correct a too soft or too hard negative.

#### Solar Prints.

The following method of making solar enlargements is suggested by Hildebrand, in "Der Photograph":—

Milk .....	20 ozs.
Glacial acetic acid .....	$\frac{1}{2}$ oz.

Mix, stir well, and filter, and then add to the filtrate:

Potassium iodide .....	140 grains.
Potassium bromide .....	34 grains.

Paint the solution over the paper and dry as quickly as possible.

The prepared paper can be either floated on the following bath, or it may be painted on:—

Silver nitrate .....	42 grs.
Distilled water .....	1 oz.
Glacial acetic acid .....	65 minims.

The paper must be exposed wet, and it is from three to four times slower than slow bromide paper. The developer is:—

Pyro .....	3 grs.
Water .....	1 oz.
Glacial acetic acid .....	40 m.
Citric acid, 10 per cent. solution.....	4 drops.

## THE ACTION OF ALKALIS IN ORGANIC DEVELOPERS.

The following paper, by M.M. A. and L. Lumière, in the *Revue Trimestrielle*, contains a number of experimental data on a point which has been the subject of much discussion at one time or another. The paper is preliminary to a second, which we have in type for publication in a later issue of the B.J.P.

It is generally admitted that the rôle of the alkalies or their substitutes in the developers is to saturate hydrobromic acid, which is set free by the action of the hydrogen, provided either directly by the reducer, or by the decomposition of the water under the action of the reducer, on the bromine of the silver bromide.

Reeb has recently disputed this hypothesis, and has assumed that the alkalies form with the reducers saline compounds, which are subsequently decomposed by the hydrobromic acid.<sup>1</sup> He has admitted that a substance possessing a developing power, cannot develop the latent image, if it possesses a saline constitution, or could give at the moment of development a salt of such a basic nature that it could saturate the hydrobromic acid.<sup>2</sup>

In the two preceding hypotheses, the quantity of alkali necessary to develop ought to be the same. In effect, the alkali, whether free or combined with the reducer, always saturates the same quantity of hydrobromic acid. There is then a great disproportion between the quantity of alkalies practically used, and that which is necessary according

to the above hypotheses. Hence these hypotheses did not satisfy us. In the present experiments we have tried to explain the rôle of the alkalies in the developers by elucidating the following points.

1. What is the mean quantity of hydrobromic acid set free in the development of a gelatino-bromide plate of given dimensions? Should there be in the developer the theoretical quantity of alkali to saturate the hydrobromic acid? What ratio exists between the reducing power of a developer containing that quantity of alkali and the quantity capable of producing the maximum effect? Is this ratio identical for the same developer with the caustic alkalies and the alkaline carbonates, and with the same alkali does it vary with the nature of the developer?

2. In the same developer can a given weight of alkali be replaced by an equimolecular weight of another alkali, or its substitutes, to obtain the same reducing power? In the opposite case, what ratio exists between the quantities found and the equimolecular weights?

3. Are the ratios between the weights of the various alkalies, which impart to a developer a given reducing power, the same for all developers?

4. Finally, can one obtain the same reducing power in the same time by using the weights of the different reducers proportional to their molecular weights with a given quantity of alkali?

5. What is, in short, the rôle played by alkalies in the developer?

#### The Experiments.

To determine the mean quantity of hydrobromic acid which is formed during development of a 13 x 18 cm. plate for example, six plates of

(<sup>1</sup>) Reeb Bull. Soc. Franc. 1904, p. 324.

(<sup>2</sup>) It cannot be conceived how this hypothesis can be strictly applied to those basic developers, such as paraphenylenediamine, the reducing power of which is considerably increased by the addition of alkalies, and with which one cannot admit the formation of salts with alkalies.

size were exposed to a subject, the larger proportions of which brilliantly illuminated. After development, fixing and washing, films were stripped and then treated with nitric acid to dissolve silver. The gelatine was destroyed by prolonged boiling, and the silver calculated as chloride, and results obtained were:—

Silver chloride .....	0.3652 gm.
Or silver .....	0.274 gm.

of alkali. In the first case, the development was very slow, about 1½ hours at 70 degrees F., the negative was not dense nor yet fogged. In the second case the duration of development for the three first plates was 6, 12, and 28 minutes respectively. The fourth plate only gave a very weak image, but one must take into account the quantity of developer removed by each plate.

The experiment was repeated, replacing the potash by the corre-

The proportion of aldehyde and acetone are indicated by volume (cc. for 10g lithia caustic).

Ammonia has been omitted as it gave rise to dichroic fog.

The proportions of caustic alkalis were carefully determined by titration, and correspond to exact quantities of KOH, NaOH, LiOH, as the commercial preparations are very variable in composition.

corresponding to hydrobromic acid 0.2052 gm. for six 13 x 18 plates, or 0.0342 gm. for each 13 x 18 plate, a quantity saturated by 0.02366 gm. of caustic potash.

We tried whether, with this small quantity of potash, it was possible to develop a 13 x 18 plate, using hydroquinone, and also whether our 13 x 18 plates could be developed with four times the quantity

sponding quantity of caustic soda 0.017 gm. The results obtained were practically the same, but on replacing the caustic soda by an equimolecular weight of carbonate 0.023 gm., the reducing power proved to be slightly less.

When the weight of the reducer strictly necessary to form the hydrobromic acid, which would neutralise this quantity of alkali,

0.023 hydroquinone to 0.017 caustic soda, the reducing power was practically nil. The addition of an excess of alkali to the same quantity of hydroquinone one gave a developer, of which the reducing power was very weak.

We have determined out one part the quantity of caustic, soda for example, and alkaline carbonate with which the reducing power ceases to increase for developers containing the usual quantities of reducer and sulphite. These results are shown in Table I.

We have tried the reducing power of a hydroquinone developer, containing 10 gms. of hydroquinone and 40 gms. of anhydrous sulphite, using each time 75 ccs. of solution, and adding the following quantities of alkali.

No. 1.—0.017 gm. of caustic soda .....	Quantity to exactly neutralise the hydrobromic acid formed in developing a 13×18 plate.
No. 2.—0.023 gm. of carbonate of soda.....	
No. 3.—0.56 gm. of caustic soda .....	Quantity for 75 ccs. of developer corresponding with the maximum reducing power.
No. 4.—2.639 gm. of carbonate of soda.....	

The duration of development to obtain images of equal density was as 120:1 for Nos. 1 and 3, 1 and as 60:1 for Nos. 2 and 4 with the carbonate.

### The Equivalence of the Alkalis.

We have tried whether with a developer, hydroquinone, for example, the same reducing effect could be obtained after the same duration of development, all other conditions being equal, by replacing the weights of the alkalis contained in the developer by equimolecular weights of the different alkalis and their substitutes.

Under these conditions the caustic alkalis alone gave the results: the alkaline carbonates and their substitutes, such as trioxymethylene,

impart to developers a reducing power which varies, and is inferior to the caustic alkalis. This last was also tested by systematically increasing the quantities of the alkalis.

The effect of such alkali or its substitute was employed in increasing quantities. In each series the proportions were chosen which gave the same density after the same time, and the plates were compared and from the results obtained the quantity of each alkali was modified to obtain identical results.

We have confirmed that one can always adjust a developer to the same reducing energy with the alkaline carbonates and their substitutes, as with the caustic alkalis, but only if one takes from two to eight times, the quantity indicated by their molecular equivalence.

The preceding tests were made with the principal commercial developers.

Table II. shows the results of our tests. All the numbers are reduced to the equivalent of 10 gms. of caustic lithia, which has the lowest molecular weight.

We found that with glycin that the addition of a quantity of alkali less than 1 gm. to every 2.5 gms. of glycin only gave a very feeble reducing action, and markedly less than when one used an alkaline carbonate. Quantities of the alkaline carbonates below those stated in the table acted weaker than the caustic alkalis. The numbers given are those which should not be exceeded. With paraphenylenediamine, on the other hand, the addition of caustic alkalis gave a much more energetic action than the carbonates.

A. AND L. LUMIÈRE.

<sup>1</sup> These ratios are not absolute. They naturally vary with the dilution of the alkalis used for Nos 1 and 3, and also with the proportion of hydroquinone which these solutions contain. For this reason exact strength of the solutions is stated.

## THREE - COLOUR PROCESS WORK.

[Abstract of a lecture and discussion at the Croydon Camera Club on March 21.]

MR. A. J. NEWTON, in accordance with a promise extracted on a previous occasion, gave a lucid exposition of three-colour process work. The club rooms for the time being were transformed into a veritable exhibition of process colour work, principally by the students of the Bolt Court School. In addition, such well-known firms as Swain, Hentschel, Andre and Sleigh, Eyre and Spottiswoode, were strongly in evidence, the Continent being also represented by Angerer and Göschl, Albert, and others. With so many admirable examples of a rapidly advancing art, it would be invidious to draw comparisons. A three-colour collotype by Mr. Holley, junr., however, compelled attention by its remarkably close resemblance to a water-colour drawing, from which it was evidently copied. In fact, by artificial light, it would have been difficult to have discovered that it had not come straight from the artist's hands, the indefinable "something" generally lost in reproductions of works of art, being in this case almost, if not quite, retained. Another exhibit, comprising a print from half-tone blocks, with a similar print beside it, printed from electrotypes from the original blocks, showed how duplicate blocks can be obtained with but infinitesimal loss. A fairly close inspection would, moreover, have failed to reveal the process employed for the reproductions, the assistance of a magnifying glass being required to resolve the cross-hatchings. It is many years since Mr. F. E. Ives lectured at the Croydon Camera Club (of which he is an honorary member), and the advances made since then were well illustrated by some superb and realistic stereo pictures, shown in the chromoscope. During the evening, Mr. Newton also showed some excellent slides by the Joly, Lumière, Sanger-Shepherd, and other processes.

The lecture itself opened with a simple explanation of the Young-Helmholtz theory of trichromatic vision, as exemplified by Clerk-Maxwell and others, and the methods of colour reproduction by positive, and subtractive, synthesis. Lantern slides and paper prints fell under the latter class, being pigment processes, pigments acting by absorption, some colours being absorbed, whilst others were transmitted and reflected. Half-tone blocks, lithography, and collotype were the processes generally employed. The last, though affording very beautiful results, was, unfortunately, somewhat uncertain, and, from a commercial point of view, could not compete, as

regards cost, with three-colour blocks in this country at present. Broadly speaking, the method of production of the process blocks was as follows:—Three negatives of the coloured original to be reproduced were taken behind coloured light-filters, under well-known conditions. Transparencies were then made from the negatives, and from the transparencies the half-tone printing blocks were secured. This was known as the indirect method. In some cases it was possible to dispense with the intervening positives, the colour record and screen negatives being made at one operation. This was termed the direct method. In either case the blocks were printed on paper in complementary colours, using as transparent inks as possible, the three images being superimposed in exact register. Any deficiencies in correct colour translations were made good by "fine etching" of the block, a lengthy job at the best, and requiring much skill. It was a pity they were compelled to use "bathed" plates, or collodion emulsion. Dry-plate manufacturers had not yet recognised there was sufficient demand for plates which would fulfil the somewhat exacting requirements of the three-colour process; indeed, they had paid very little attention to the matter. He hoped Messrs. Wratten and Wainwright would remove this difficulty. Mr. Newton then passed round for inspection some fine carbon three-colour prints, and also a capital pinatype print by a student of the Bolt Court School. The excellence of the latter aroused much interest, as when "pinatype" was demonstrated by Mr. Scholl before the members in the autumn the specimens then shown hardly indicated its inherent and undoubted possibilities. With pinatype, Mr. Newton said, there was the advantage that one could easily obtain a matt surface, and once a good result had been secured, duplicate prints could be readily made from the same plates.

In the discussion which followed, Mr. C. E. M. Bennett asked whether Mr. Newton had tried the three-film plate brought out by Dr. Smith, of Zurich. Mr. E. A. Salt inquired how three-colour work stood commercially in relationship to lithography, and their relative advantages and disadvantages. Lithography, with its multiple printing, had produced results which, in his opinion, "three-colour" might rival, but never excel. Lantern slides and paper prints might both be "subtractive," but they had essential differences, notwithstanding. A projected slide on the screen, com-

ed only light actually transmitted by the pigments. On the other hand, with paper prints, the pigments not being perfectly transparent, not only transmitted a certain proportion of the incident light, which was reflected back by the support, but also directly gave light, by surface reflection, a certain amount of light. The order in which the pigments, or printing inks, were superimposed, would, he thought, seem to be a disturbing factor. With water-colour paints, which, he was ready to admit, were far behind the special printing (in point of translucency), if a wash of transparent yellow was laid over a transparent wash of blue, a totally different shade of green would be obtained than in the case of the operation reversed. With three colours, one laid over the other, their relative order seemed all the more relevant, and, in addition, as they each partly directly-reflecting and transmitting light, he did not see how Mr. Mees, or any one else, would calculate, except in the roughest manner, the necessary conditions for accurate colour reproductions. Moreover, if fine etching was necessary for colour correction, this seemed to indicate the necessity of the interposition of an artist. So far as he knew, his mathematical friend made no claim to be an artist, and no amount of science would enable one to become an accurate judge of colouring. The speaker also asked whether the process block maker was tied to three colours. A four-colour process had been suggested, and if better results could be obtained, why not use four, or more.

Mr. Mees said he made no pretence to being an artist, but he did not think that he could accurately measure the colour absorptions and reflections of pigments, which could readily be expressed in the form of a graphic curve. The amount of reflection obviously depended on the angle at which the surface was viewed. There was a great difficulty in persuading the ink makers to produce satisfactory inks for the purpose they had in view; they had, however, inks which transmitted and reflected 75 per cent. of their colour. Alluding to an observation made earlier in the evening by Mr. Newton as to the tendency of bichromated films to become insoluble, he said that he had found that unless they were dried and exposed within four hours, insolubility began to set in; they, moreover, had to be developed in water at a comparatively low temperature, or the geloid support cockled. This naturally affected registration. Mr. Newton, in reply to Mr. Bennett, said he had given Dr. Mees's three-film plate a trial. It appeared to be attended with considerable manipulative difficulties. Dealing with the points raised by Mr. Salt, he pointed out that although the colouring of a reproduced lithograph might be, and indeed frequently was, better

than a three-colour print, yet unless extreme care was taken, and many printings made, the delicate touches of the artist were apt to be lost. His drawing and technique were better rendered by photography than by lithography. With small prints of good quality, the advantage, as regards expense, was also in favour of the camera and process blocks. He had heard of one litho. picture which had received upwards of seventy distinct impressions, an elaboration which most craftsmen would think unnecessary. The interposition of an artist for fine etching was not required, he had a tendency to try and improve on the original instead of endeavouring to produce a facsimile. It was, however, necessary that the fine etcher should have a keen perception of colour. As to the suggested employment of more colours than three, the current accepted theory did not indicate a larger number. On the other hand, the use of only three colours necessitated a very delicate adjustment, which slight errors—even variations in the temperature of the printing room, for instance—could easily throw out of balance. In this connection, some had advocated a "black key"; this would certainly to some extent cover a slight want of register, and give much greater depth in the blacks than could usually be obtained by the superposition of three coloured inks. If all conditions were theoretically perfect, screens, plates, exposures, and printing inks, perfect reproductions would be mechanically possible; but, of course, conditions were never perfect, and some compensation had to be made by hand work. The three-colour process could not, therefore, be considered to be quite automatic. Even the best and most highly sensitive plates had deficiencies, their steepness of gradation, varying with different portions of the spectrum. In practice this would to a certain extent be compensated by alteration of exposure, and time of development.

The President (Mr. W. H. Smith), in proposing a hearty vote of thanks to Mr. Newton, said how pleased he, and, he felt sure, all the members were, to see Mr. Wratten, senr., amongst them that night. His hearers would be interested to know that Mr. Mees had joined Messrs. Wratten. He thought that the association of their able scientific worker, and popular fellow member, with one of the best firms of plate makers, would be very greatly to the advantage of photographers in general, and to the colour-process man in particular. The last observation of Mr. Smith was, no doubt, prompted by the fact that a well-exposed snapshot through a red screen had been passed round for inspection, the negative being taken on a new plate shortly to be placed on the market by Messrs. Wratten and Wainwright, and having a red sensitiveness to 6700.

## A NEW ARTIFICIAL LIGHT STUDIO.

following abstract of an article by Herr Rösl in the current number of the "Photographisches Wochenblatt" will be of considerable interest to many who have been considering the adoption of

which, so far as we are aware, has not yet been tried for portraiture, and that is the flaming sunlight arcs, in which the carbons are impregnated with various salts, with the result of a brilliant yellow

Fig. 1.

sort of artificial lighting for studio work, and in the face of the latest advances in electric illuminants, such as the Cooper-Hewitt, the arc lamp, and the Westminster enclosed arc lamp, more attention should be paid to this subject. There is, however, one type of lamp,

Fig. 2.

light. Many of these lamps, as will doubtless be recalled by our readers, are used for outside shop illumination.

First of all, a stout wood framework, as shown in Fig. 1, should be constructed, and a semi-circular roof erected on the openwork sides, so that a kind of cage in the form of a tunnel is formed. The

measurements are approximately: Breadth *a-b*, 13ft.; length *a-c*, 19½ft.; height to the top of the arch, 14ft. The studio, in which the above arrangement was erected, had sufficient length to give ample working distance.

The above described frame is now covered inside with white linen, so that it finally presents the appearance shown in Fig. 2. Right at the end will be seen a heavy plush curtain, which is useful for head and shoulder pictures; when this is drawn on one side the background is exposed.

The lamp used in this studio consists of two arcs, burning side by side, which are supported on a movable pillar and are enclosed in a reflector, by means of which the light is directed in any desired direction, the front being also provided with a matt diffuser.

The interesting feature about this lamp, however, is that the light is never used direct, but always directed against one of the sides of the tunnel and thence reflected on to the sitter. In order

Fig. 3.

to control the lighting the sides of the structure are provided with dark grey linen curtains, each about 180 inches square, and with which the whole of the sides can be covered up or only a part, so as to leave a reflecting surface.

As in an ordinary studio, the light is controlled by drawing the curtains, so in this studio control of the light is obtained in the same way, and the top light is also treated the same.

The author states that the results obtained by this method of working cannot be distinguished from ordinary daylight lighted work. Every possible effect is easily obtained, and he considers that this is a great advance in studio construction, and that extremely short exposures are required with a lens working at *f*/4.5.

#### THE "SINGLE-PICTURE EXHIBITION."

THE proposed exhibition by members of the Professional Photographers' Society of New York, appears to be meeting with enthusiastic approval among the leaders of the profession in the United States. From the current issue of "The Photographer" we find the views of some half-dozen of the well-known men. J. C. Strauss, St. Louis, thinks that "the plan will be of considerable benefit to photographers, especially in the smaller communities."

A. T. Proctor, President of the Photographers' Association of Pennsylvania, writes:—

"Your exhibition idea is an excellent one. It is going to awaken a new line of thought of untold value to your members. That photographers need a stirring up on just these lines. At first glance it is rather a stiff proposition to put up to a man, but as soon as you appreciate the fact that you are supposed to send an example to represent your idea of a certain picture you would want to deliver to a customer at a given value, it becomes easy and interesting."

J. S. Schneider, a former President of the Photographers' Association of America, welcomes the suggestion as a means of enabling photographers to judge how much good work can be afforded for a given price.

J. George Nussbaumer, also a former President, credits the "single picture" scheme, with the ability to make business.

"The plan is so unique and practical that it must appeal to any one who is alive to his best interest as a business photographer," is the opinion of C. L. Lewis.

Charles Wesley Hearn, the President of the P. A. of A., prophesies a success for the exhibition on the ground that "the professional, if he be sane, must always remember that *his profession is a business*, and that just as much attention must be paid to business as to making pictures, and that both of these attributes are combined in the exhibition."

The following list of questions to be discussed at the coming meeting of the Professional Photographers' Society of New York has just been announced.

The members are requested to read the questions carefully and be prepared to state their views concisely:

- I.—How can the ticket swindlers best be discouraged?
- II.—Under what circumstances is the photographer warranted in offering a free sitting?
- III.—Is there ever a time in the photographic business when it pays to cut prices?
- IV.—In the long run, does it pay to "speculate" larger plates or pictures?
- V.—How can a uniform and equitable rate be fixed on school and class work?
- VI.—What ratio in price should the one-half dozen bear to the dozen photographs?
- VII.—What is the best basis upon which to estimate the cost of production?
- VIII.—Is there any reason why a uniform minimum rate of 5 dollars a dozen should not be established by the legitimate portrait photographers of the country?
- IX.—Should a fixed charge be made to cover the cost of the sitting where no order is placed? What is the best procedure in such cases?
- X.—Does it pay to copyright photographs of prominent subjects?
- XI.—How should individual members proceed against fake enlargement men?
- XII.—How can the show-case be made a stronger business-puller?
- XIII.—Should the photographer advertise in programmes, directories, newspapers, etc.? If so, should he mention prices?
- XIV.—Do we adopt the same measures for the prevention of waste in the studio as practised in other business establishments?
- XV.—Is it not an error in judgment to rely upon an extensive line of mounts for differentiation in styles and prices?
- XVI.—How does the present price of material and apparatus in the U.S. compare with prices in other countries?
- XVII.—Has the so-called "Demonstrator" outlived his usefulness?
- XVIII.—In hiring a boy to work in the studio, do you make inquiry to see whether or not he is the proper material out of which a photographer can be made that will do you credit? Should this not be the procedure?
- XIX.—How can the P. A. of A. be made of real and practical benefit to photography?
- XX.—How can the photographic magazines be made more interesting to the professional photographer?
- XXI.—Do the restricted trade conditions now in force affect the business of the professional photographer?
- XXII.—As between mercury vapour and arc lights which has the advantage as to efficiency when cost of installation and operation is taken into consideration?
- XXIII.—Does the business picture exhibition contain more of interest to the photographer at large than those modelled on artistic lines?

AN accident by which some sixteen or eighteen men were more or less hurt occurred last week at Woking in the printing works of Messrs. Unwin Brothers, the publishers. A photographer, anxious to secure a group of the large staff of employees, had had a staging erected some thirty feet long and ten or twelve feet high, arranged in about six tiers, on which the group could pose. The men were taking their places, and about a hundred were on the staging, when the framework collapsed in the middle, and those upon it were precipitated in a heap to the ground.

## PHOTOGRAPHING THE FUNDUS OF THE EYE.

PROFESSOR E. DIMMER, in a paper published in a recent issue of our contemporary, the "Keystone," reviews his work in the photography of the eye for ophthalmic purposes, and states that by the system which he adopts at present he is able to get negatives instantaneously, i.e., in one-twentieth or one twenty-fifth of a second. The following is a description of the apparatus employed and the method of working.

The arrangement by which I have got rid of the confusing reflexes and flare is by placing a plane mirror S (see figure) exactly in front of the patient's pupil at an angle of forty-five degrees with the optical axis. This mirror receives the whole of the condensed light from the source L, and reflects it into the eye through half the pupil, so that the light which passes out of the remaining half of the pupil is alone employed to form the image. In order to obviate the formation of reflexes near the edge of the mirror, due to half of the pupil being hidden, half of the camera objective is blocked out by an opaque diaphragm O2. This lens O1 is a Zeiss Planar objective of 160 mm. focus. In the diagram the light from the lower half of the pupil will pass through the upper half of the Planar lens, while the light proceeding to the lower half of the Planar is screened off by the diaphragm. It will be noticed in this my last model that the very large aperture of the Planar  $f/4.5$ , which I may add is 45 mm. in diameter, takes in the whole of the rays emerging from the half pupil, so that none is wasted. The image of the half pupil formed by the first objective O is, of course, half-moon shaped, and so large that in my former instrument the decentred lens (an astigmat of only 9 mm. diameter) invariably cut off a portion of the light.

The frosted screen used in the illuminating apparatus is now abandoned, so that the image of the electric arc I is formed in the plane of the open diaphragm D. From this diaphragm an inverted image of the illuminating system B is formed in the half of the pupil effected in the mirror S, by which means the area of the background of the eye which appears in the photograph, and no other part, will be illuminated.

The shutter V1 lies immediately behind the diaphragm D, while the second shutter V2, which I have changed to a roller blind, lies just in front of the plate P. By means of a mirror (not shown in the figure) the image of the fundus can be observed up to the very moment of exposure. A squeeze of the rubber ball T causes the mirror to flap up, and at the same moment both shutters, controlled by a single wire, are opened and closed again by an electric current. The eye is thus exposed a trifle longer than the plate, i.e., about one-eighth second.

The front part of the instrument between the two objectives must never be touched. The focussing due to anomalies of refraction in the examined eye is obtained by racking the focussing screen P in or out, as the case may be.

The position of the eye to be examined is obtained by getting the patient to fix the image of a flame (seen in a mirror placed before him) with his other eye, or else by means of a cross wire placed in the illuminating zone, which is observed by the patient with the eye about to be photographed. By this latter method a patient possessing only one eye can have it photographed.

In emmetropia the image taken by the direct method has a diameter of about 30 mm. The original negatives show an enlargement of three diameters, so that the largest picture shows a magnification of nine to eleven diameters. I have shown that by lateral and vertical movements of the patient's eye a much more extended area can be photographed. This extension, after repeated trials, is found to be about 10-12 times the diameter of the disc in the meridional line. The construction of the instrument has been undertaken by the firm Zeiss, which has met my wishes in the fullest way, so that all the

requirements necessary have been carried out and no further adjustment or alteration in the illuminating apparatus has been found to be needed. The two large tubes,\* one of which contains the condensing lenses for illumination, the other the two sets of objectives for the camera, are firmly fixed to each other, but nevertheless are capable of coarse and fine adjustment for the eye. All that is necessary to take a picture is to adjust the arc light (which is identical with that employed by Zeiss for his projection camera), so as to illuminate the fundus to enable the image to form a focus on the plate in the camera slide. Last year I used a Nernst lamp, but this I have been able to replace by the more powerful arc light, so that a photograph can now be taken in an instant even by the merest tyro.

## PHOTOGRAPHY AND TAILORING.

In the "Photo Era" an account is given of a photographic method of taking measurements for clothes which is put forward as the original invention of a Mr. Gerhard Moe, of Wisconsin. We may quote what is written of it, while reminding our American friends that the method of the line screen between the sitter and the camera is a well-known device for the photographic registration of dimensions, and has been used in France for human measurements for scientific purposes:—

According to Mr. Moe, the photographic outfit necessary for these measurements is of the simplest kind, consisting of an ordinary 7 by 5 camera with rectilinear lens of medium focal length. As a preliminary to the making of the measurements, the camera is first fixed in a position which it should always occupy when in use for this purpose. At a distance of from 8 to 10 ft. from the front of lens, according to the focal length of the instrument, a line is drawn upon the floor, which represents the position always to be occupied by the subject being photographed. The proper position once being determined, a large screen strung with white silk running in opposite directions so as to form squares of exactly 2 in. between the threads is placed over the line previously marked on the floor, thus occupying the position later on to be taken by the subject. This screen is photographed upon the plate, and a permanent grating or screen (with squares of exactly the same size shown in the reproduction of the larger screen) is affixed to the back of the camera, immediately in front of the sensitive plate or film.

Once the size of these squares is ascertained and provided for in the camera, no matter what that size may be, the large screen is done away with, as each square shown in the succeeding photographs will represent exactly 2 in. on the subject being photographed, if placed in the same position before the camera. A large sheet, ruled diagonally with heavy black lines, or a fabric made up of red and white stripes, serves as a background behind the figure being photographed, and helps materially to read the marking on the finished print. At the back of the camera, inside, is arranged a hinged door or sliding cut-off, which covers either half of the plate during exposure of the other half. Thus both views of the figure are produced upon the same plate, and are made under the same conditions in every case.

By making a reproduction of the large screen on a transparent film and interposing it before the negative in the printing frame, the same results may be obtained as with the screen in the camera. It is, of course, important in all work of this kind that the size of grating used in front of the plate or film corresponds exactly with the image of the large screen as it appears upon the ground glass of the camera.

A camera of any size may be used, and a lens of any focal length, provided it is rectilinear, or an outfit especially prepared by the inventor which does away with the making of a special screen and grating.

An exhibition illustrating "Georgian England" opened yesterday at the Whitechapel Art Gallery, and will remain open until May 9, 1906.

\* These tubes are indicated in the diagram. The entire apparatus is very massive and heavy, being about 5 ft. to 6 ft. in length. The wheels in the apparatus are attached to long screws, which enable the instrument to be raised or lowered, turned laterally, or moved nearer to or further from the patient's eye, whereby much time is saved, as the adjustments can be instantly effected.

## ARTISTIC LENSES.

INFORMATION on the practical properties of the anachromatic lenses of MM. Puyo and de Pulligny being sought by a number of our readers, we may translate the substance of a circular issued by one maker of them, M. Turillon, of Paris, who is manufacturing from M. Pulligny's calculations.

The mounting used for these lenses is the same as usually employed for portrait lenses, namely, with rack and pinion, and either iris or waterhouse diaphragms are fitted. The largest aperture is  $f/5$ , and each succeeding stop requires double the exposure. On the inner tube is engraved the necessary anachromatic correction, which should always correspond to the focal length of the lens used.

Each objective is fitted with a pair of symmetrical meniscus lenses, a single meniscus and a plano-convex lens. The two latter may be used by themselves; the focus for each is then 12 inches for a  $7\frac{1}{2} \times 5$ , and 16 inches for a  $9 \times 7$  inch plate.

When only one lens is used it is advisable to place it at the back of the mount, so that the convex side is turned towards the plate. If it were placed in front, the convex side would be towards the sitter.

All other combinations may be added according to whether the camera has a long or short extension. If large sized images are required, it is advisable to mark the anachromatic correction for such focus on the tube.

The symmetrical meniscus lenses, when used together, one in front and one behind, with their convex surfaces outwards, may be used for all subjects with full aperture of  $f/5$ .

The plano-convex and meniscus lens, with full aperture of  $f/10$ , may be used for landscape, full length portrait and groups, it gives more diffusion at the same aperture.

When the objective is used in its original mounting, the rack and pinion should be moved till the front of the piece cut out of the outer tube butts up against the diaphragm, and then the anachromatic scale engraved on the inner tube should be found, and the lens racked back till the back edge of the aperture coincides with the O, in which position focussing should be done. Then the anachromatic correction should be made by racking the inner tube back till the edge of the aperture corresponds with the point of the scale which is equal to the distance of the sitter, and the exposure should then be made.

## Exhibitions.

## CAPE TOWN PHOTOGRAPHIC SOCIETY.

THE Exhibition of the Cape Town Photographic Society, held in the City Hall, from February 3 to 10, has been a success in many respects. It has put before South African workers a selection of leading European work, and has thus given an incentive to the practice of photography throughout the Colony. It was not expected, we believe, that the exhibition would prove a financial success, and the present depression at the Cape has not given the promoters any occasion to point to their prophecies as unduly pessimistic. However, we understand that a deficit of well above £100 is faced by the Cape Town Photographic Society with *esprit de corps*, and that the success in every other direction has amply rewarded the executive and its secretary (Mr. A. J. Fuller) for their labours of organisation. In addition to the competitive classes, the exhibition included a selection of work by the Linked Ring and by the North Middlesex Photographic Society, and it also embraced the examples of marine photography by F. J. Mortimer shown at the Royal Photographic Society's Exhibition last year. The awards in the competitive classes were as follows:—

Gold medal for best picture in the show.—Charles R. Armstrong.

Silver medal for the most artistic picture in Section A.—J. P. Edwards.

## SECTION A. (PHOTOGRAPHERS IN SOUTH AFRICA).

Landscapes (South African).—Medals: Charles R. Armstrong, J. P. Edwards. Special mention: E. Peters, J. P. Edwards. Honourable mention: Mrs. V. Rayner, Sydney Taylor, E. J. Steer.

Seascapes (South Africa).—Medals: Sydney Taylor, Victor Romilly. Special mention: Dr. G. M. F. Nellen. Honourable mention: E. Campion, Geo. Greene, Victor Romilly.

Genre and Figure Studies.—Medals: Charles R. Armstrong, A. Elliott, Miss H. Watkins. Honourable mention: E. Peters, A. Elliott, Sydney Taylor.

## SECTION B. (INTERNATIONAL AND OPEN).

Landscapes.—Silver medal: G. J. T. Walford. Bronze medals: W. H. Fowkes, A. J. Fuller, J. E. Latham. Special mention: Geo. Easonsmith. Honourable mention: Lewis Lloyd, F. A. Tinker, I. Petschka, E. S. Maples, Fred Judge, J. E. Latham, Ed. Garrone, F. J. Whitworth, G. Castruccio.

Seascapes.—Silver medal: W. Clayden. Bronze medal: Edgar G. Lee. Honourable mention: William Norrie, William Clayden, Rev. A. E. Bor.

Architecture.—Silver medal: Edgar G. Lee. Bronze medal: H. K. Campion. Special mention: W. A. Clark. Honourable mention: G. J. T. Walford, J. P. Edwards, Fred Coop, H. R. Campion, W. A. Clark.

Genre and Figure Studies.—Silver medal: John Moffat. Bronze medals: Alfredo Ornano, Ed. Garrone. Special mention: John Moffat, T. H. Stoward. Honourable mention: H. W. Lane, Edgar G. Lee, Walter Norgrove, L. Ussher, F. Coop, A. Minnie, G. Castruccio, Carl Sciutto.

Still Life.—Silver medal: A. E. Henley. Honourable mention: A. E. Henley, S. G. Kimber.

Lantern Slides.—Silver medal: Edgar G. Lee. Bronze medal: F. Nemirowsky. Honourable mention: Fred G. Tryhorn.

Stereoscopic Paper Prints.—Silver medals: A. J. Fuller, H. Wormleighton, Sydney Taylor.

Scientific and Technical Photography.—Silver medal: E. H. V. Melville.

Lantern Slides.—Silver medal: William Farren.

## Photo-Mechanical Notes.

## The Price of Copper.

THE rising price of this metal is becoming serious to photo-engravers, as they have seen the metal in polished sheets advance from about 1s. 2d. per lb. to about 1s. 8d. and more within the last month or two. In spite of rumours as to a ring controlling the supply, there seems to be every reason for thinking that the increasing demand for this metal is bound to keep the price high, unless some unexpected source of supply should appear. The financial supplement of the "Times" for March 5 last devotes a long article to the subject of copper prices and consumption, and shows that last year the price of crude copper rose by £11 per ton, and refined by £16 10s. a ton, though the production has increased by 75,000 tons, or  $11\frac{1}{2}$  per cent. The consumption, however, has absorbed all this, and much that was held in stock, the increase being attributed to the 60,000 tons that China had taken for new coinage, and for the very large amounts of copper that are required nowadays in shipbuilding, electricity, and agriculture.

## The Economy of Stripping.

While copper remains at this high price, and the money obtainable for the finished blocks shows no tendency to increase, it behoves engravers to study every means of economy. Stripping wet collodion negatives is one of the ways that means no small saving of metal. One firm recently found that it could save 20 lb. of copper weekly by introducing this method. And, of course, there is further economy all round, for less time is taken in printing, and in the rough etching. And if no prism is used, then the exposures may be shorter, and there is economy of space in the camera room.

The best method of stripping is to allow the negative to dry, to rule it round with a knife to size required, then take a piece of paper cut roughly to size of film, soak this in water, lay on the negative, allow to remain for a minute or so until the film has been penetrated by the water, then with a penknife lift one corner of the film, and it will come away

tached to the covering paper. If it has now to be reversed is transferred to another piece of paper; if not, it is laid on directly on the large glass upon which the number are to be stripped. This glass should first be covered with a film of starch paste or gum, in order to make the films adhere satisfactorily. This method is quick, and avoids the use of rubber and flexible collodion.

# A New Process for Reproducing Plans.

For some time there has been in use in Paris a method for reproducing plans quickly and true to scale by means of a kind of graph process. A similar method has now been worked out by Messrs. J. Hall and Co., of Westminster, who are selling licences to work their process. It consists of preparing a jelly, which is spread evenly over glass or metal and allowed to set. A blue print is then made from the tracing, which, without washing to develop, is laid upon the jelly. After a short time it is removed, the plate is then inked over with a roller charged with printing ink; the ink then takes on the lines. Paper is now laid on and slight pressure applied. When the paper is removed it will be found that a perfect impression in black lines is left on the paper. The process does not need an unlimited number of copies, but it is stated that twenty can be pulled without difficulty.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for patents were made between March and 17.

**POSING PLATES, ETC.** No. 5,926.—Improvements in means of carrying and exposing dry sensitive plates of films in the camera. Robert Ballantine, Arthur Ballantine, Hew Ballantine, and John Linstrum, 37, West Nile Street, Glasgow.

**THEATRE EXHIBITION.** No. 6,228.—A piece of apparatus to be used with an optical lantern, to show slides without the need of darkening the room. Arthur John Henry Brown, Ebor School, Bexhill-on-Sea.

**EMATOGRAPHS.** No. 6,324.—Improvements in automatic light cut-off for cinematograph projectors. Robert Royou Beard, 10, Trafalgar Road, Old Kent Road, London, S.E.

**PHOTOGRAPHS.** No. 6,512.—Improvements in photographic exposure shutters. Alfred Woods, 4, South Street, Finsbury, E.C.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 3d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**POD STANDS.** No. 18,332. 1905.—The invention consists of a tripod stand, consisting of a triangular metal head, with a central bore, to each side of which is hinged a metal plate, which is connected to the top of the tripod leg, so that the latter can be spread out as in an ordinary tripod. The three plates are secured to the triangular plate by a circular locking plate. Alexander McLeod, 171, Queen Street, Brisbane, Australia.

**STEREOSCOPIC PROJECTION.** No. 3,998. 1905.—The invention consists of a system in which the stereoscopic effect on the screens is witnessed without observing the projected pictures alternately with the right and left eyes. The claim is for a stereoscopic lantern with a revolvable or travelling shutter or shutters so arranged and worked that the stereoscopic pictures are alternately projected in periods separated by a distinct period of total obscuration of both pictures equal in duration to the duration of either period of exposure or projection. The author describes various forms of shutter, disc, and band, and points out that in each the essential feature is the alternate exposure or projection of the respective pictures, together with the total obscuration of both pictures, equal in length of time to the exposure or projection of either picture. The invention is stated to differ

from those where it has been proposed to project stereoscopic pictures superimposed upon a screen without the aid of a device to place before the eyes of an observer, in such an arrangement, the pictures have been projected in quick succession without the measured periods of the tentative total obscuration of both pictures, as is the case in the present invention, and which is found to produce a complete and perfect stereoscopic effect upon the pictures projected. Walter Henry Everson, Royal Colonial Institute, Northumberland Avenue, Westminster.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—  
TELEPHOTO LENSES. No. 4,523. 1906.—Photographic tele-objectives. Carl Zeiss.

## New Materials.

Barnet "Medium Ortho" Plates. Made by Elliott and Sons, Ltd., Barnet, Herts.

In introducing a second orthochromatic plate to share the market with the well-known "Barnet Ortho," Messrs. Elliott have had in mind the wants of those using an orthochromatic plate for landscape work, etc., with a stand camera. The new plate, to be known as the "Barnet Medium Ortho," is not by any means rapid, but it possesses colour sensitiveness of a good panchromatic plate, and should therefore meet with favour for many purposes where short exposure is not a *sine quâ non*. Its other properties evidence the carefully controlled manufacture which we expect from the Barnet factory. The plates develop quickly, are without fog, and are evenly coated. These qualities, apparent to a user of the plates, are equally evident to those familiar with sensitometric specifications such as we have been accustomed to give in reviews of new plates.

The following, obtained by the methods of Mees and Sheppard, explained in a recent series of articles in our pages, apply to the particular sample of the "Medium Ortho" submitted to us by Messrs. Elliott (Batch No. 8,169).

Inertia (H. and D., pyro-soda) 1.26.

$\gamma_{100}$  (density-giving power of the plate) 2.53.

K (velocity constant of development with standard ferrous oxalate developer) .113.

t<sub>1</sub> (time necessary to obtain a standard gradation of 1 with the standard developer, i.e., the time for which the plate should be developed with that developer) 4.4 minutes.

The new plates are placed on the market at the popular price of 1s. per dozen quarter-plates.

**Pinacyanol- and Pinachrome-bathed Plates.** Made by Wratten and Wainwright, Croydon, Surrey.

General experience and practice having long recognised the fact of the superior orthochromatic action of a dye when applied as a bath to a plate in comparison with its action as a constituent of the emulsion the question of the commercial supply of such bathed plates has been raised and representations made to manufacturers. Technical and commercial obstacles, unknown, perhaps, to many making the request, are in the way of the introduction of new products of this description, but it is interesting to find that a response has at length been made by the old-established firm of Wratten and Wainwright, who two years ago placed three-colour workers under an obligation by the introduction of the "Verichrome" plate. They are now taking further advantage of the newer isocyanines and of the method of treating dry plates so as to secure their maximum effect, by issuing "Pinachrome-bathed" and "Pinacyanol-bathed" plates. These plates, tested by exposures to the spectrum, give the characteristic sensitiveness conferred by bathing plates in the dyes, the "pinachromes" giving a practically even sensitiveness beyond the blue to about the orange red, 6,300, A.U., and the "pinacyanols" still further in deep red to about 6,800 A.U. The spectrum of the latter to unscreened acetylene gives the usual marked maxima at 5,900 and 6,400, and the gap in the green at 5,000 to 5,600, but exposed to daylight the plate gives a remarkably even deposit from 5,000 to 6,500, showing only very faint

maxima. Of course, the blue sensitiveness is predominant, but this spectrum shows that with a yellow filter to cut this down it would be possible to get an almost even spectrum photograph of daylight, extending to the C Fraunhofer line, which for some purposes is exactly what is required. Both these plates are extremely rapid, and in our hands have proved far and away the best commercial plate we have ever used for three-colour work, equal, in fact, to any home-bathed plate.

It is advised that the plate be developed in the dark—certainly one could not use a red, however deep, for the pinacyanol plate—but it is not difficult to develop in absolute darkness, since Messrs. Wratten state on the instruction card placed in each box the time of development at a certain temperature necessary to give good results.

These are not the only particulars enclosed with each packet of plates. The ratios of exposure, for several sets of commercial filters are also stated, in addition to speed numbers and the ratio of blue sensitiveness to red sensitiveness which we have been accustomed to give in these columns. The offer of assistance in this way to the user is in the nature of an innovation, and we may therefore reprint a specimen card as showing the method by which Messrs. Wratten and Wainwright hope to facilitate the work of their patrons:—

### BATHED PLATES.

To be developed only in absolute darkness.

#### Batch No.

Sensitiven ss. H. & D. 50.  
Watkins 220.  
Wyn e F120.

(NOTE.—This sensitiveness is measured to daylight; by artificial light it is greatly increased, for incandescent gas about 20 times compared with ordinary plates.)

Blue Sensitiveness  
Ratio ————— 1:2  
Yellow Sensitiveness

Ratio for ————— three-colour filters—

Blue Green Red

Daylight

(The Blue filter requires — times as much exposure as the plate without a filter.)

In respect of the mechanical properties of the plates, we can only add—and we can give no higher praise—that they are up to the standard of the other dry plates made by Messrs. Wratten and Wainwright. The prices of the two new plates are 2s. per dozen quarter-plate, 4s. 3d. per dozen half-plate, and 8s. whole-plate.

THE current issue of "The Bromide Monthly" is nothworthy in issuing as a supplement a negative on "Rotograph" negative paper, a manufacture of the Rotary Photographic Company which has steadily grown into favour for the making of large negatives for carbon printing and other purposes. Four separate subjects are distributed through the issue of "The Bromide Monthly," and the opportunity thus afforded of proving the quality obtainable in a paper negative is one which may be seized with advantage. A single copy is sent by the Rotary Company on receipt of three penny stamps.

A VARIETY of mouldings is sent us by Messrs. Daniell Bros., 38, Morley Road, Lewisham, accompanying a list of prices for frames 24 by 20, 20 by 16, and, in some cases, 25 by 16. The prices for the frames impress us as being moderate—from 40s. to 60s. per dozen—and the selection of mouldings ought to enable Messrs. Daniell's customers to suit all tastes in the matter of framing, from the ornate gilt to plain wood in various art shades.

### DEVELOPING FORMULÆ.

Do not wet the film before applying the developer.

Any developer can be used except those containing ammonia. We recommend the following:

METOL HYDROKINONE DEVELOPER  
Metol .. .. . 10 parts  
Hydrokinone .. .. . 5  
Sodium Sulphite .. .. . 100  
Sodium Carbo ale (cryst.) 100  
Water to .. .. . 1,000

Time of development with above solution minutes—

	for	Portrait	Architecture	Landscape
Temp. F. 50°	3'0	4'0	5'0	
" 65°	2½	3'0	4'0	
" 80°	1½	2½	3½	

Time of development for three colour negatives.

	Red filter	Green filter	Blue filter
Temp. F. 50°	3½	4'0	4½
" 65°	2½	3'0	3½
" 80°	2	2½	2½

### CATALOGUES AND TRADE NOTICES.

As announced in our "Correspondence" columns, the Platinotype Company have been obliged by the continuous rise in the price of platinum, to raise the prices of platinotype papers. Both classes of paper, black and sepia, on whatever raw paper, will now be sold at the following uniform rates:—

Packets of Twenty-Four Pieces.

Quarter-plate .....	2s. 3d.	Half-plate .....	5s. 6d.
5 x 4 .....	3s. 3d.	7½ x 5 .....	6s. 6d.
6 x 4½ .....	4s. 6d.	1-1 plate .....	8s. 6d.

Packets of Twelve Pieces.

10 x 8 .....	6s. 6d.	12 x 10 .....	9s. 6d.	15 x 12 .....	14s. 0d.
--------------	---------	---------------	---------	---------------	----------

The prices of tubes of sheets, 26 x 20, will be as follows:—

Three sheets .....	9s. 6d.	Twelve sheets .....	36s. 6d.
Six sheets .....	18s. 6d.	Twenty-four sheets .....	72s. 0d.

Postcards will be sold at 12 for 2s. 3d. The new prices, it will be seen, represent a very considerable advance on those hitherto in force, but the aim of the company is admittedly to supply the best paper that can be made, and with that desire they have had to yield to the inevitable in manufacturing the same article whilst one important raw material is four times its price.

In "What Can be done with the Goerz Lens," the firm of C. P. Goerz issue a booklet (free on application to 4 and 5, Holborn Circus, London, E.C.), which, with its illustrations, is an incentive to good technical photography, and for that reason alone to be commended for perusal. The text goes with the half-tone reproductions, and gives a good deal of information on the qualities desirable in lenses for landscape, architectural, flashlight, and other photography.

AN informative illustrated booklet reaches us from the Emil Busch Optical Company, 35, Charles Street, Hatton Garden, describing the use of telephoto lenses for portraiture, etc., and the properties of the Busch "Bis Teler," a new telephoto lens, in particular. The special features of the lens are its small size, simple optical construction, and its price (48s. for half-plate size.)

Mr. S. H. Fry, of enlarging fame, announces his change of address to larger quarters at Frisian House, 5, Highbury Grove, London, N.

A new list of ferrotype apparatus and materials has just been issued by Mr. Fallowfield, 146, Charing Cross Road, London, W. It includes, we note, a number of new accessories, and novel designs of mounts and frames for ferrotype photography.

THE Marvels of Photography.—An article of apparently American origin on this subject appears in our handsome contemporary, "The World's Work and Play," and will interest photographers from its reproduction of the first photographic portrait, that of Miss Dolly Draper, made in 1840, alongside that of Mr. George Eastman, a fitting conjunction of past and present. The writer is laudatory in his references to photographic portraiture as represented by Stieglitz and Steichen, though we cannot allow to pass uncorrected his statement that the latter's photographs were admitted to the Paris Salon. It will be remembered that though selected by a preliminary committee they were thrown out by the General Jury of Admission.

A CIRCULAR from J. Lizars, of Bold Street, Liverpool, supplies particulars of the classes in elementary and advanced photography which are held at that establishment, a species of enterprise which reflects credit on the firm's activity in responding to the needs of its amateur patrons.

At Mr. Hanfstaengl's gallery in Pall Mall East (writes the "Globe" art critic) there is now on view a series of colour-engravings which can be commended to the attention of people who are interested in the processes by which facsimiles of works of art can be produced. These engravings are printed in colour from photogravure plates, and they are remarkably successful as reproductions of the pictures selected, because they suggest faithfully enough not only the colour but also the technical qualities of the originals. By the use of photography the actual brushwork and paint surface are closely imitated in the prints, and the subtleties of colour gradation are not less correctly realised by the method adopted of preparing the plate for printing. The process is not simply mechanical; it allows the printer scope for the display of his individuality and taste, and, therefore, the results attained have a more than ordinary right to serious appreciation.

## New Apparatus, &c.

the "Aptus" Numbering System for Midget Photography. Made by Sharp and Hitchmough, 101-103, Dale Street, Liverpool. The system of numbering each negative in making a series on one plate has passed through several forms in the hands of Messrs. Sharp and Hitchmough until its arrival in the convenient shape in which it is embodied in the present apparatus. One form which was, and is still, employed consists in a frame, bearing a number at its upper extremity, which is suspended behind the sitter so that the figures appear at the upper edge of the negative. This position is justified by a balancing weight which the operator moves whilst passing the sitter. Such a system, though valuable, is less satis-
